FOREWORD

The widespread use of the automobile for private and business transportation as well as the rapid increase in the use of trucks and buses for commercial purposes has created traffic problems in cities large and small which were unknown a few years ago. Recognizing the fact that traffic problems in Middletown, particularly the parking problem, had gradually reached the point where a scientific study was necessary, a local traffic committee was formed at the suggestion of the state FERA administrative organization with a view to sponsering the Middletown traffic survey, and FERA funds were allotted for this purpose.

This committee consisted of Professor Charles R. Hoover, chairman, George H. Boothroyd, Eugene F. Clark, F.B. Fountain R.S. Lyon, Van Buren Moody, Fred W. Shearer, Fred N. Smith, and R.H. Wilcox, representing the town selectman, the Chamber of Commerce, the local ERA, the service organizations and the city and town schools. These men have given a great deal of time and thought as well as every possible co-operation to those in direct charge of the survey, and whatever achievement that is forthcoming as a result is largely due to their efforts.

Altogether about forty people were employed during the winter months, the organization consisting of a director, an office manager, a senior engineer, two junior engineers, two draughtsman, two stenographers, and a staff of field clerks. Practically all of these people were worked under the budget system used by the Connecticut state ERA social service and excellent co-operation was obtained from the social service organization in obtaining and placing so-called "white Collar" workers where they could do their best work.

The state furnished able administrative assistance from the state ERA engineers office working through Mr. F.W. Hutchins Regional Engineer. Expert advice on traffic problems was furnished by the ERA planning division of engineers through traffic advisors, Mr. J.G. Hayden and Mr. R.N. Grunow whose assistance contributed in a large way to the success of the project.

Fine co-operation was also obtained from the city officials including Mayor Leo B. Santangelo, R.W. Wilcox, First Selectman and local Relief Administrator, Director of Public Works, Allen R. Schaeffer, and Chief of Police Charles A. Anderson.

Acknowledgement and thanks is hereby tendered to the following organizations who contributed the use of valuable equipment: Central National Bank, Chamber of Commerce, Farmers and Mechanics Bank, Guy, Rice and Davis, Middletown National Bank, Remington Noiseless Typewriter Corporation, Travellers Insurance Company, and Wesleyan University.

REPORT OF THE MIDDLETOWN TRAFFIC SURVEY

INTRODUCTION

Middletown the principal city in Middlesex County lies in the heart of a wealthy trading area and is therefore the focus of all vehicular traffic in this section. In addition, the city is in the approximate center of the state of Connecticut with main highways entering it from six directions. The winter traffic entering and leaving the city each twenty-four hours on these routes averages 12,000 cars. Much of the shore traffic in the summer time from the north-western part of the state passes through the city thus increasing this figure about 40 per cent, and bringing the total summer traffic in and out of the city to an estimated 17,000 cars per day.

The survey indicated that approximately 5000 cars are being parked in the business district, during the ordinary winter business day, an average of about 500 cars per hour. On Saturdays, including the evening shopping hours, this total is about 8600 cars an average of 610 cars per hour. The average winter traffic flow on Main Street in the central section of the city is approximately twelve thousand cars a day with a proportionate increase in the summer time.

It is obvious that the Middletown business district is handling a much larger volume of traffic in proportion to its size than many other cities. The city is very fortunate in having a Main Street of unusual width and length which makes the traffic problem much simpler than it could be otherwise.

The growth of traffic in the past ten years has been so great that it is very important to anticipate as far as possible the effect of increased motor vehicle registration with the resulting traffic during the next ten years. In 1924, there were 2894 motor vehicles registered in Middletown, while in 1934 there were 4958, an increase of 71%. The increase in the state of Connecticut closely parallels this figure. In addition, the gasoline consumption per car has gradually increased indicating that the total motor vehicle mileage will be greater this year than ever before. Except for a drop in 1933, the trend in the past five years has been gradually upward and it is safe to assume that with increasing prosperity Middletown's traffic problems and those of the state will become more and more difficult.

Traffic is now one of the major problems of every city and its importance justifies long range planning for the future.

MIDDLETOWN PARKING SURVEY

Parking has been one of Middletown's major traffic problems for a number of years not because of the lack of facilities but rather because of the careless parking habits of the people. Lack of adequate parking regulations and enforcement have been contributing factors. These are conditions which have gradually grown upon the community largely because the unusual parking facilities in Middletown's business district have made close regulations of parking unnecessary until recent years. Other cities of similar size were forced by a rapid growth in motor vehicle traffic to pass strict parking regulations at a much earlier date.

Parking conditions in Middletown have reached the point where it is difficult to find parking space in the central section of the city on the afternoon of the average week-day, and during the peak hours on Saturdays it is practically impossible. At these times, double parking has become a general practice thus slowing down the normal traffic flow and creating a general chaotic condition. Although Main Street and some of the adjoining streets have had a two hour parking limit for a number of years, it has not been generally observed by the public. These unrestricted conditions offered an unusual opportunity from a statistical standpoint for a parking study because practically everyone could stay as long as necessary to accomplish the purpose of their visit to the business district Therefore, the results presented herein give an accurate cross-section of the parking habits of the community.

OBJECTIVES:

The Middletown parking survey had the following general objectives:

1. To determine the parking habits of the public both in the two hour limit zones and on the unrestricted streets of the business district.

2. To determine the number of habitual and occasional overtime parkers and classify them as to occupation, place of residence, and number of violations over an extended period of time.

3. To collect general data on parking such as the number of double parked cars with and without drivers, the number of commercial vehicles at the curb or double parked, the number of cars opposite hydrants, prohibited zones, and driveways.

4. To consider the best location of Bus Stops, the advisability of other parking plans for Main Street, and to make general constructive suggestions.

PROCEDURE:

Parking studies were made on the following streets; Main St., from Hartford Ave. to Union Street, Washington Street from Pearl to Water Street, and Court Street, College Street, and William St., from Broad to Water Street. Some data was taken on Liberty Street but the study was discontinued because the results did not warrant carrying it further.

All parking spaces on these streets were numbered at thecurb and corresponding numbers were placed on data sheets having a horizontal column for each parking stall. The location of all other curb spaces such as at hydrants, prohibited zones, and driveways was also layed out on the data sheets so that cars parking at these points could be recorded. Special symbols were used to indicate improper parking, commercial vehicles, double parked cars with drivers and double parked cars without drivers. Each observer had his data sheet layed out in advance for the section assigned to him

and all that he had to do was to record the number of the car that occupied each stall at the proper point on the data sheet at regular intervals throughout the day, usually from 8 A.M. to 6;30 P.M. on week-days and from 8 A.M. to 10:30 P.M. on Saturdays. Readings were taken every half-hour during the period of the main survey. Thus, the data sheets were layed out for readings at 8:00 8:30, 9:00, 9:30, etc.

Since the principal purpose of the main survey which was made through the month of December was to collect data on overtime parking, the entire business district had to be checked at one time for a period of several days. Checks were made on nine week days, and three Saturdays between November 28th, and December 22, 1934., a period of heavy shopping preceding Christmas. Apparently the fact that the survey was in progress had no deterrent effect on overtime parking because a daily analysis shows that the number of overtime parkers remained about constant thruout the course of the survey.

Later, during the month of March 1935, it seemed desirable to make additional parking studies to check the data obtained in Dec. This offered an opportunity to obtain data taken at fifteen minute. intervals which is fundamentally more accurate. This point was recognized at the start of the main survey but due to lack of personnel and the fact that the entire business district had to be checked at one time over a continuous period, the December study could not be made this way. However, the two methods agreed with a surprising degree of accuracy on most points.

Occasional counts of the number of cars parked during the day were made on Broad Street, Church Street, Crescent Street, Liberty Street and at the various parking spaces behind stores and office buildings to determine in a general way the average number of cars being accommodated in these areas.

One of the major accomplishments of the survey was the preparation of a parking map three feet by five feet, showing the location of all parking space in the business district as well as hydrants, prohibited zones, driveways, traffic lights, traffic rotaries, and public or private parking lots with their entrances. The entire map was drawn to scale and all dimensions actually taken from the street, thus filling the need of the city for an accurate map of the downtown business district. This map has been and will be very useful in studying various parking layouts, analysing data, etc. A full sized blue and white cloth print colored to show prohibited parking zones, traffic lights, and hydrants, has been placed on file with Chief of Police, Charles A. Anderson.

The parking map on the next page is not an exact copy of the original map. It is included here as a substitute, because of the difficulty in obtaining a reduced readable copy of the large map. This small map was prepared primarily for the use of the public in locating no limit parking space. Details, such as the number of spaces in each block, the accurate location of hydrants, yellow zones, and driveways, have necessarily been ommitted.

During the course of the December and March surveys, approximately three hundred thousand readings were taken on one hundred and fifty thousand vehicles. This provided enough data to assure accurate results based on averages. For the purposes of analysis, Main Street was divided into three zones, which were determined after the parking density on each main street had been computed as shown graphically in Figures 1 and 2.

Since the two central blocks on Main Street, namely, from Washington to College Street are most densely parked and too about the same degree, they were grouped to-gether and called Zone 1. The block immediately north of Zone 1, namely, from Washington to Liberty Street and the block immediately south of Zone 1, namely from College to William Street also show approximately the same degree of parking, and they were grouped to-gether and called Zone 2. The remaining blocks, namely from Hartford Avenue to Liberty Street and from William Street to Union Street were grouped to-gether as Zone 3. This method of grouping Main Street parking areas is similar to the zoning method used in determining parcel post rates.

Each of the east-west streets crossing Main Street, was considered as a separate unit thus giving a total of seven different units which permitted a detailed analysis of any part of the business district. In addition, the entire Main Street, and the entire business district were each taken as a unit for an analysis of these areas as a whole.

All data was summarized and averaged on standardized forms for the average week-day and for the average Saturday. These are

included as a part of this report following Page 30. Therefore the summarized data for any zone, of the whole can be obtained from them. The same tabulation method was employed in summarizing the fifteen minute interval study made in March and these are also included in this report following the above data.

The numbers of all overtime parked cars were listed in a card index with one card for each car showing the owner's name and address, the time parked, the duration of parking, and the location of the car for each infraction observed. Excellent co-operation of the Motor Vehicle Department in securing the names and addresses permitted accurate analysis and classification into the following five groups.

1. Habitual overtime parkers employed in business district.
2. Miscellaneous habitual overtime parkers from the business district.
3. Occasional overtime parkers from the Middletown area.
4. Occasional overtime parkers from Middlesex County outside of Middletown.
5. Occasional overtime parkers from the remainder of Conn.

Considerable data was accumulated relative to the location of prohibited zones, bus stops, and limited parking areas, in the business district. Other parking plans such as, double row center parking were given careful analysis and will be discussed in further detail.

DISCUSSION OF RESULTS:

Considering first the parking situation as a whole in the business district the following figures obtained during the course of the survey will give a general picture of the problem. Except as otherwise noted these figures are totals obtained during a period of fourteen days, twelve days in December and two days in March

Total Number of Overtime Parked Cars	5005
Total Number of Cars Parked Over Two Hours	7101
Total Number of Cars Parked Opposite Hydrants, Prohibited Zones, and Driveways	1906
Total Number of Cars Double Parked Without Drivers	408
Total Number of Major Parking Infractions	7319
Total Number of Cars Improperly Parked at the Curb	6187
Total Number of Cars Parked per Average Week-day	5000
Total Number of Cars Parked per Average Saturday between 8 A.M. and 10 P.M.	8600
Average Parking time of all Legally Parked Vehicles on Main Street.	38 Min.

Overtime parking constitutes 68.4% of the major parking infractions, parking opposite hydrants, zones and driveways is 26%, and double parking without drivers is 5.6%. While such infractions as the latter two are more serious in the eyes of the law than overtime parking, they are largely the result of overtime parking. In other words such an enormous amount of overtime parking reduces parking space to the vanishing point and automatically encourages these offenses. Therefore, any remedy which will increase the number of available parking spaces will at the same time reduce double parking and parking opposite prohibited areas.

Percentage-wise, the number of overtime parked cars in terms of the total number of cars being parked varies in different areas from 5.1% to 14½% depending on the day of the week, the weather and other factors, The following table gives a general idea of the variation for the average week-day and the average Saturday.

PERCENT OVERTIME PARKERS TO THE TOTAL

LOCATION	AV. WEEKDAY	AV. SATURDAY
Main Street Zone 1	5.1%	7.0%
Main Street Zone 2	7.3%	7.8%
Main Street Zone 3	5.8%	8.4%
Court Street	10.9%	14.5%

UNRESTRICTED AREAS

PERCENT PARKED OVER TWO HOURS TO TOTAL

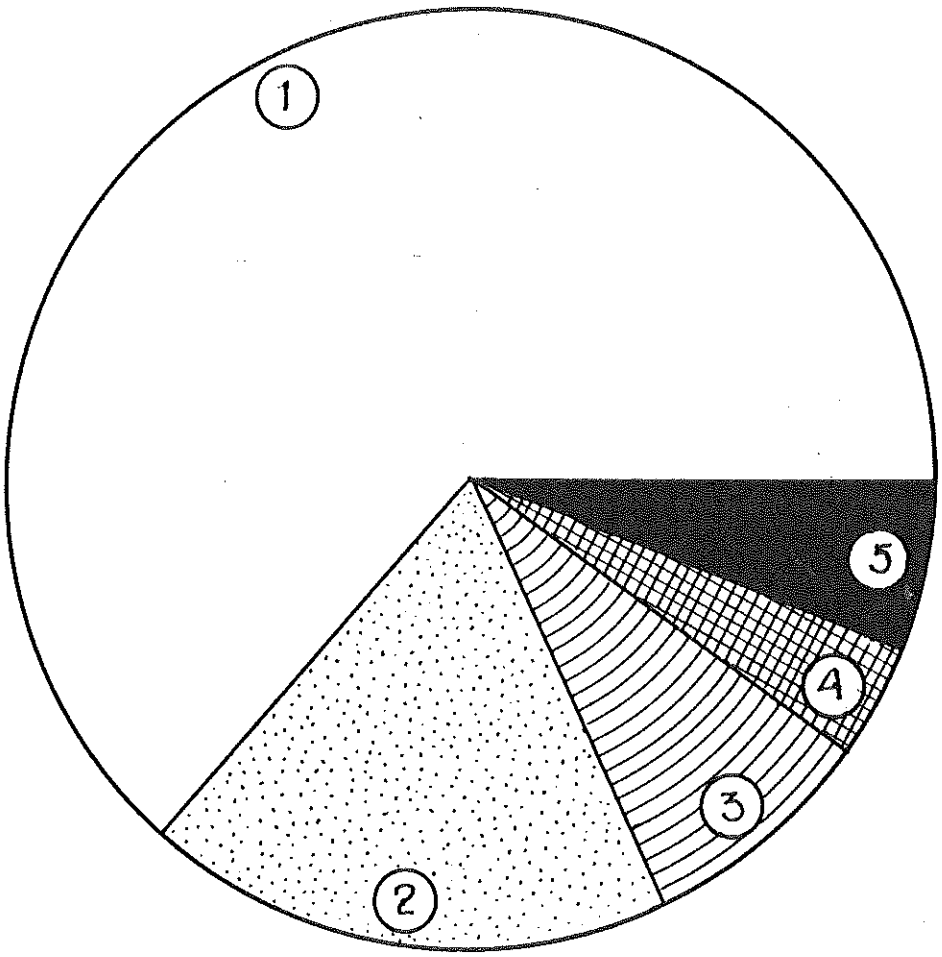
	Av. Week Day	Av. Saturday
Washington Street	28.1%	27.0%
College Street	30.0%	34.8%
William Street	25.0%	16.6%

Although the overtime percentages are small, their effect in terms of occupied useable space is much greater. In order to analyze this, let us consider the parking habits of the general public as illustrated on Figure 3, which shows the parking period distribution on the average week-day for the entire Main St. Note that 63½% of all cars average one-half hour parking time and that 81.8% of all cars parked an average of one hour or less. This leaves 12.2% who park between one and two hours and 6% who park overtime. While these figures apply to Main Street as a whole almost identical results were obtained in each separate zone. The habits of Main Street parkers are remarkably uniform along the length of the street. These figures also apply closely to Saturdays when the percentage of overtime parked cars is a little higher which slightly brings down the percent of those parking one hour or under.

Figure 4, illustrates the proportion of the total space hours that each class of parker uses on Main Street during the average week-day. The space hours are calculated by multiplying the number of cars involved times the average length of time parked. This is the true measure of the proportion of the total space which each group of parkers use.

FIG.-3

PARKING PERIOD DISTRIBUTION
AVERAGE WEEK DAY
ENTIRE MAIN STREET

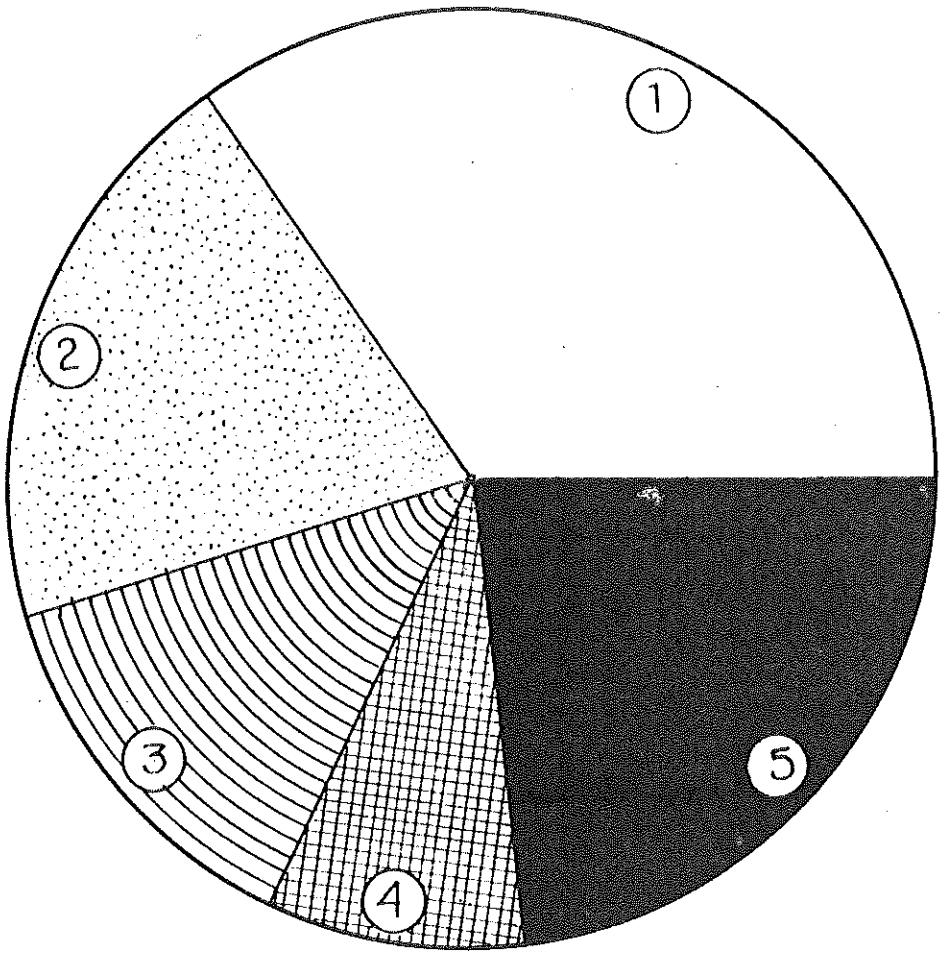


LEGEND

(1)	63.5%	OF CARS PARKED	½ HR.
(2)	18.3%	OF CARS PARKED	1 HR.
(3)	8.1%	OF CARS PARKED	1½ HRS.
(4)	4.1%	OF CARS PARKED	2 HRS.
(5)	6.%	OF CARS PARKED	OVERTIME

FIG.-4

SPACE HOUR DISTRIBUTION
AVERAGE WEEK DAY
ENTIRE MAIN STREET



~ LEGEND ~

(1) - CARS PARKED ½ HR. USED 34.7% OF SPACE HRS.

(2) - CARS PARKED 1 HR. USED 20.% OF SPACE HRS.

(3) - CARS PARKED 1½ HRS. USED 13.3% OF SPACE HRS.

(4) - CARS PARKED 2 HRS. USED 8.9% OF SPACE HRS.

(5) - CARS PARKED OVERTIME USED 23.1% OF SPACE HRS.

Thus, the overtime parked cars (6% of the total number) illustrated in Figure 3 actually use 23.1% of the total space hours. It is significant to note that the 18.2% who park over one hour are using 54.7% of the total space hours occupied on Main Street. In other words, a comparatively small number of people are responsible for the congestion and parking difficulties experienced by everyone who tries to park on Main Street. In considering these facts it should be emphasized that they represent the actual parking habits of the community unaffected to any appreciable extent by parking restrictions. It is reasonable to assume that any parking plan which fits the habits of a large majority will be successful

Let us examine Figure 5 which illustrates the percentage of space hours used by the various classifications of overtime parkers. Habitual parkers were those observed parking overtime more than once during the course of the twelve days in December while occasional parkers were those observed only once. The habitual group averaged about six infractions apiece, the range per car being from two up to nineteen infractions. Note that nearly 50% of the overtime space hours are used by merchants, in the business district or their employees. The group classified as habitual parkers-miscellaneous in the business district, are those who could not be classified as full time employees and others who were temporarily working in the business district. Those listed as, occasional parkers from the Middletown area, appeared only once in the course of the December check and are probably shoppers of those having temporary business. Other occasional parkers from Middlesex county and the remainder of Connecticut who

4. OCCASIONAL PARKERS — MIDDLESEX COUNTY OUTSIDE OF M'D'TN 5.3%
5. OCCASIONAL PARKERS REMAINDER OF CONNECTICUT 15.8%

occupy a total of 21% of the overtime space hours can only be classified in this general way.

It is evident that people living in the general Middletown area which includes Portland and Cromwell, use practically 80% of the overtime space hours. Since the overtime space hours used by out of town people constitute only 20% of the whole, it would be practical to adopt a liberal enforcement policy for this group should it seem desirable.

In terms of the actual number of people involved, about 60% of the overtime parkers are from Middletown area and about 40% from out of town. In a community like this, there is naturally a considerable overlapping of these two groups because many people living in towns such as Durham, Higganum, and Middlefield, etc. are listed from out of town, but they actually regard Middletown as their center of business activity.

To analyse the three zones into which Main Street is divided, a careful study of Figures 6,7, and 8, will be helpful. The solid line of Figure 6, represents an hourly count of the number of cars actually on the street in Zone 1, between 8 A.M. and 10 P.M. This includes all double parked cars and cars opposite hydrants, prohibited zones and driveways. It gives some indication of the actual demand for parking space that exists in Zone 1 on a busy Saturday. There are two peaks, one at 11 A.M. another at 8 P.M. when the number of cars standing on the street far exceed the total number of parking spaces in these two blocks. In addition there was a period at four O'clock for perhaps an hour when the demand exceeded the capacity.

FIG-8

It is an actual fact that for satisfactory parking, the number of spaces in use should never exceed 80% of the total. This has been demonstrated time and time again during the course of the survey. Furthermore, maximum space circulation seems to be obtained at about an 80% parking level.

The eight o'clock peak illustrated in Figure 6 indicates that there were 34 more cars in Zone 1 than the total number of parking spaces, and that 77 more cars were on the street than there should have been for a satisfactory parking condition. This gives us something in the way of a theoretical objective to work to in making parking regulations.

The dotted curve on Figure 6 marked "Enforced Two Hour Parking" indicates the estimated number of cars each hour which would be in Zone 1 assuming that the present two hour regulation were stirctly enforced and that all of those who are now parking over two hours remained for exactly two hours. The lower dotted curve marked "Enforced One Hour Parking" indicates the condition which would result with strictly enforced one hour parking, assuming that all cars who now park over one hour remained for exactly this period. It is realized that these curves are theoretical, and that the actual space demand in Zone 1 is much greater at times than the curve indicates, because many cars seek parking space there without finding it.

One hour parking in Zone 1 would theoretically open up an average of 58 spaces and would increase the space circulation on Saturday approximately 28%. In practice, the effect of one hour

parking would be to automatically force the long time parkers entirely out of Zone 1, also the small group of four per cent who park two hours would find it necessary to seek parking space elsewhere. Thus, much more than 28% of the space would actually be available for shoppers and short-time parkers. Naturally, the Main Street merchants in this area as well as the public would profit a great deal by the increased space circulation afforded by one hour parking.

Parking Regulations in Connecticut Cities

Before making any recommendations for parking in Middletown let us consider what limits have been adopted in other Connecticut cities. To make the comparison, information was requested from the Police Department of each of the cities listed in the accompanying table. The points covered were as follows; parking time allowed in the most congested business districts, parking time allowed immediately adjacent to the congested business district, amount of the fine for overtime parking, degree of enforcement of parking regulations, and whether or not the city in question had sufficient personell to strictly enforce the parking regulation

The replies to these inquiries have been condensed and tabulated in the table on the following page. It is apparent that the majority of these cities allow from 15 to 45 minutes parking in the congested business district and that none of them allow over one hour. Even in the less congested areas only two cities allow more than one hour at points where a parking restriction is used.

PARKING REGULATIONS IN CONNECTICUT CITIES

CITY	PKG. TIME CONGESTED BUSINESS DISTRICT	PKG. TIME ADJACENT BUSINESS DISTRICT	FINE FOR PARKING VIOLATIONS	ADEQUATE POLICE FORCE	DEGREE OF ENFORCEMENT
MERIDEN	15 to 30 Minutes	30 to 60 Minutes	1st.-None 2nd.-$2.00 3rd.-$5.00	NO.	MODERATE
DANBURY	60 Min. 15 at Banks 5 at P.O.		$1.00 Forfeited by Bond	NO.	RIGID
STAMFORD	60 Min.	None	1st.-$1.00	YES	RIGID
BRISTOL	20 to 30 Minutes	1 Hour	$2.00 for all violations	NO	RIGID
BRIDGEPORT	60 Min.	Prohibited in front of Theatres	$1.00	YES	RIGID
NEW LONDON	30 Min. 10 Min. in front of P.O. & Banks	1 Hour 12 Hour in residential	1st. Warned 2nd. $2.00	NO	MODERATE
WATERBURY	45 Min.	1 Hour	$1.00	YES	RIGID
NEW HAVEN	30 Min. on both sides of st. 30 min. on narrow streets	No Limit from 7 A.M. to 7 P.M. 3 Hours from 7 P.M-7AM	$1.00	NO	RIGID
GREENWICH	60 Min.	2 Hours	$3.00	YES	RIGID
MANCHESTER	1 Hour Part of one street in center 10 Min.	On few streets Parking is restricted on one side	$2.00	NO	MODERATE
HARTFORD	15 Minutes 40 "	1 Hour One or Two Points 2 Hours	$1.00	YES	RIGID
MIDDLETOWN	2 Hours	No Limit	$2.00	NO	MODERATE

Therefore, if one hour parking is adopted for Main Street, Middletown would still have more liberal parking limits than most other Connecticut cities and parking facilities unequaled by any of them. It is hoped that the board of Police Commissioners will see fit to adopt one hour parking for Zones 1 and 2 and possibly for Zone 3 which can be either one ortwo hour parking.

While strictly enforced two hour parking would help slightly it can not be recommended as a real solution to Middletown's parking problem. Later as the car registration and population of the community grows it may become necessary to adopt a restriction below one hour. Since the average parking time of all legally parked vehicles was less than 40 minutes, a 40 minute parking limit on Main Street would not be unreasonable, particularly in Zone 1.

Figures 7 and 8, plotted to the same co-ordinates as Figure 6 indicate that the parking density in Zones 2 and 3 is not nearly as great as in Zone 1, although Zone 2 becomes congested on Saturdays during the three peak periods. It is recommended that any change put into effect for Zone 1 be also applied to Zone 2. Otherwise, the natural result would be to force the overflow from Zone 1 into the adjacent blocks of Zone 2, thus creating an unfair condition there.

However, Zone 3, because of its low parking level even on Saturdays could be left with a two hour parking limit which would provide about 170 spaces on Main Street where the out of town visitor could park more than one hour.

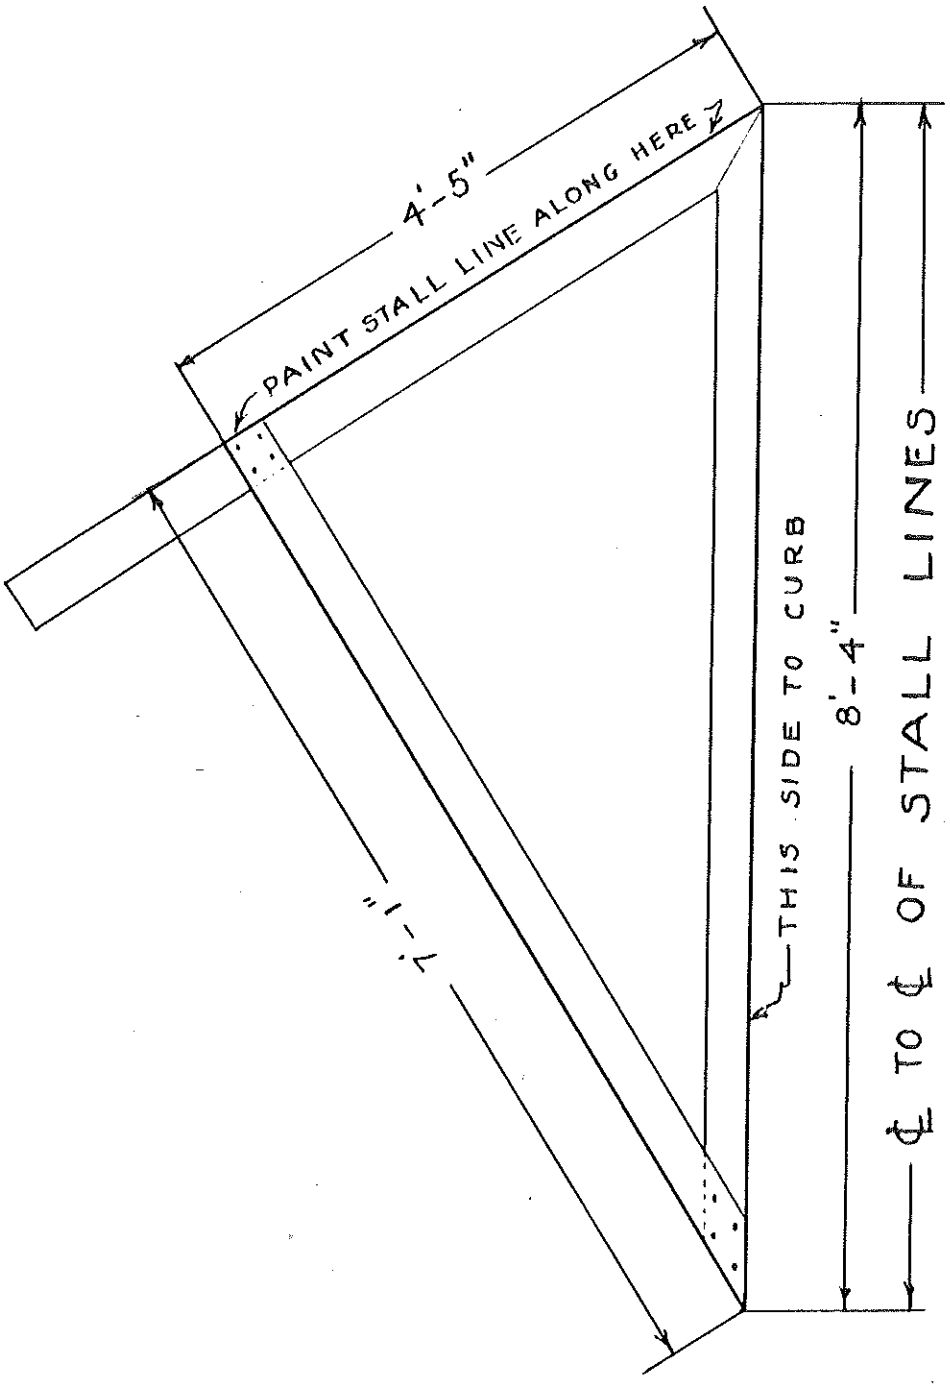
Parking Stall Layout

Because of the fact that a one hour parking limit on Main Street would open up a large percentage of the parking space it would be possible in this event to use a slightly easier parking angle, without feeling the necessary loss of a few parking spaces. A check up of the present parking angles indicated that they vary from 55 to 70 degrees. After a trial of various experimental stalls, it was decided that one with an angle of 58 degrees which requires an eight foot four inch curb space for a seven foot one inch width, would be a good stall for the average car. This stall gives an average distance between cars of about 16 inches and permits easy parking from a line approximately 10 feet outside the row of curb parked cars. The templet illustrated in Figure 10 will be helpful in laying out this stall. It could be used throughout the length of Main Street with a loss of only three percent of the present number of spaces. If a wider stall seems desirable without the loss of curb space, a 60 degree angle is recommended with an eight foot four inch curb space,which gives a stall width of seven feet three inches.

Court Street Congestion

Court Street, one of the main arteries to the business district entering Main Street at appnoximately its center, has been a source of great congestion for a number of years. Overtime parking on this street averages 10.9% on week-days and 14.5% on the average Saturday which is about twice the average for Main Street.

FIG.-10



DETAIL OF
PARKING SPACE TEMPLATE
SCALE 3/4" = 1'-0"

While the parking density on Court Street during the day time is somewhat lower than on Main Street, traffic tie-ups seem to be more frequent here than at any other point in the business district. Recent counts on the number of times per day that traffic is at a standstill at some point on Court Street average one every 7½ minutes on a week-day and one every 9½ minutes on a Saturday. This does not include the partial tie-ups from double parking, which are included in the tables below.

Delays From Double Parking	37	34	71
Total	66	84	150

More traffic tie-ups are indicated on west Court Street than on east Court Street, but the situation is very bad at both points. Most of the traffic jams occur near the centers of the blocks and they seem to be rather uniformly distributed throughout the day, after the early morning hours.

It is evident that in case a fire coincided with one of these tie-ups it might delay the arrival of the fire apparutus for several minutes. Trucks in the habit of double parking for loading and unloading purposes are the principal cause. The street is not wide enough to accommodate parallel parked cars on each side and double parked trucks in the middle without either creating a bottle-neck or an actual closure of the street. Therefore, it is recommended that serious consideration be given to the elimination of all parking on the south side of Court Street between Broad and Main Streets. For the section of Court Street between Main and Water Streets parking on one side or the other should be eliminated. There is slightly more traffic heading east than there is west on this section, but the difference is small. A one hour parking limit is recommended for the unrestricted side of Court Street between Broad Street and Water Street.

Major Recommendations Already Adopted

At the time of this writing, the Police Committee have decided to adopt the following changes in parking regulations.

1. One hour parking on Main Street thruout its entire length, from 12 A.M. to 6 P.M. on week-days and from 12 A.M. to 10 P.M. on Saturdays.

2. One hour parking on the north side of Court Street from Broad to Main Streets between the hours of 12 A.M. and 6 P.M. on week-days and between the hours of 12 A.M. and 10 P.M. on Saturdays. No person shall park any vehicle on the south side of Court Street between Broad Street and Main St.

3. One Hour parking on the north side of Court Street from Main Street to Water Street at all times. No person shall park any vehicle on the south side of Court Street from Main Street to Water Street between the hour of 6 A.M. and 6 P.M. After 6 P.M. and until 6 A.M. one hour parking will be allowed on the south side.

4. No person shall park any vehicle on the north side of Loveland Street between South Main and High Street.

With a one hour parking limit on Main Street the natural question arises "Where will those cars go who formerly parked from one to ten hours"? If parking space off Main Street can be found for this group, it will open up from 28% to 50% more space on Main Street depending on the degree to which this is accomplished. It will mean that on Saturday an average of 94 cars per hour will have to seek parking space off Main Street with a peak of 116 per hour at 8 P.M. The number of unused no limit spaces within one block of Main Street averages at least 182 per hour. In addition, within two blocks of Main Street there is an average total of 409 unused spaces. These figures do not include at least 200 spaces which are usually available behind stores and office buildings and which will furnish ideal parking space for employees. Nor do they include the Berkeley Divinity pay parking lot. Therefore, it seems that one hour parking will not create an undue hardship on anyone.

Minor Recommendations Already Adopted

Minor suggestions which have already been acted upon favorably by the Police Committee are as follows:

For the present the east-west streets with the exception of Court Street and eight spaces on Washington Street, south of Wetmore Place, will be left as they are with unlimited parking at all points where parking is allowed. This affords no limit parking space for 223 cars within an average of one half a block of Main Street between Liberty Street and William Street.

South Street at the Railroad Track

No parking is to be allowed for 75 feet from the north corner on the west side of the street. Parking here interferes with the approaching motorists view of the railroad crossing.

Intersection Church and Main Street.

A "STOP" sign is to be installed on the southwest corner of this intersection to increase the safety of the motorists entering Main Street from Church Street. No parking is to be allowed for 42 feet from the northwest corner of this intersection to permit a better view of the south bound Main Street traffic.

Corner of Liberty and Main Streets.

No parking is to be allowed on the north side of Liberty Street for a distance of 60 feet from the Main Street curb, Parking at this point blocks west bound traffic from entering Liberty Street when east bound traffic is waiting for the signal.

Hartford Avenue

The lanes and yellow curbing on Hartofrd Aveune are to be completely repainted.

Parking Stalls

The new 58 degree parking stall is to be adopted when the lines are repainted.

High Street

From Washington to Spring Street is to be a through street. Liberty and Grand Streets will be "STOP" streets at High Street.

A new parking ticket designed to facilitate checking and filing and to eliminate paper work by the police has been officially adopted. The police department have also adopted a card similar to the parking check data sheets for making their own parking checks, which will replace the old method of marking tires with chalk.

Other Suggestions

Union and Sumner Streets.

It is suggested that a white line following the center of the street is to be painted around this corner from Union Street into Sumner Street.

Painting

It is suggested that parking stall, yellow curbing, and parking signs be repainted every six months to keep them in first class condition.

Center Street.

This is the narrowest of all the streets leading into Main Street. It carries a comparitively small amount of traffic approximately 800 cars each twenty-four hours, of which about 56%

travels eastward. At present no parking is allowed on the north side. In view of the frequent tie-ups on this street with the consequent fire hazard, it is recommended that Center Street be made a one way street for east-bound travel with parking allowed on the south side only as at present.

Bus Stops

Middletown has three recognized points where thru-buses can stop. These points are at the Municipal Building, the Connecticut Co.,stop at Kings Avenue on Main Street, and the Blue Way Bus stop at the North End Fruitery. There is very little traffic congestion at the north end of Main Street where the Connecticut Company and the Blue Way buses now stop, and from this standpoint it is an ideal place for the location of a recognized municipal stop for all buses.

If possible, it would be desirable to eliminate the stopping of buses at the Municipal Building, the point now used by the Grey Line, particularly north bound buses which must stop on the left side of the street and therefore must cross the south-bound lane of Main Street traffic. The Grey Line operates from four to six buses a day which make a rest stop at this point and therefore bring a certain amount of business to the city.

At a recent conference, an official of the Grey Line pointed out that if they could not continue the use of the present stop they might be forced to make their rest stops elsewhere. To compromise, a stop just behind the Connecticut Company bus stop on Court Street was offered them. The use of this point would mean

a short walk of perhaps 100 feet for the passengers who wish to eat, but it would be much better in every other respect. It is recommended that every effort be made to persuade the Grey Line to use this point rather than the Municipal Building Stop.

Double Parking

There are two or three periods on Saturdays when double parking on Main Street with and without drivers has become habitual with people wishing to run in and do short errands. This creates a congested condition between College and Washington Streets, for a period of an hour or two at 11 A.M., 4P.M. and 8 P.M. Under the new regulations, there will be more parking space on Main St. or within a block than there has been before. Much of it is unused even on Saturday nights because most people will double park on Main Street if they can, rather than walk a block. To relieve this condition it is suggested that every effort be made to keep the traffic on Main Street moving. If the thirty or forty cars which now clog the traffic on Main Street Saturday night could be kept moving and were required to find a parking space, a much improved traffic condition would result.

Traffic Characteristics in Zone 1

Some interesting data on the characteristic traffic in Zonel is plotted on figure 9. The curve at the top of the sheet indicates the volume of traffic in number of vehicles per hour at Washington Street between the hours of 8 A.M. and 10 P.M. on the average Saturday. The solid curve second from the top indicates the parking density between these hours. This curve does not indude

FIG-9

double parked cars or cars parked opposite prohibited areas but simply indicates the number of cars actually in legitimate parking stalls. The dotted curve indicates the cars being parked each hour, which is a true measure of space circulation.

There is a definite tendency for the number of cars being parked to drop when the spaces become nearly full. This can be noticed at eleven o'clock, three o'clock, and eight o'clock. There is also a tendency for the space circulation to increase at the times when the number of occupied spaces drops down, such as at one o'clock and again at four. These data indicate that greater space circulation will normally be obtained when there are a considerable number of spaces open. It is evident that the maximum space circulation is obtained at a parking density of about 80% when 20% of the spaces are open.

Comparing the hourly traffic flow curve with the parking circulation curve, we find that there is a tendency for the peaks of these curves to occur at the same time, The low points of the spaces occupied curve occur at the same time as the high points of the traffic flow curve. These are conditions that one would normally expect.

The third curve from the top shows the number of vehicles standing in the street, not in parking spaces, throughout the day. The three peaks of this curve correspond exactly with the three peaks of the spaces occupied curve directly above indicating that at times when the spaces are practically all full, the number of cars waiting in the street plus those illegally parked immediately reaches a maximum.

The two bottom curves indicate the number of commercial vehicles parked at the curb on week-days and Saturdays. It is interesting to note that more commercial vehicles are on the street week-days and that the majority of them appear in the morning hours.

Main Street Parking Systems

Before making the final recommendations toward the solution of Middletown's parking problems, thorough study was given to the two plans of center parking outlined on Figure 11, as compared with the present system of angle curb parking.

Considering first the double row center parking plan which is drawn to scale with the proper stall angle and spacing, it is apparent that this plan offers a number of important advantages which are listed as follows:

1. It permits passenger vehicles, buses, and trucks to draw up to the curb to take on or discharge passengers or freight.
2. It divides the traffic into two lanes reducing the possibility of collisions between cars travelling in opposite directions.
3. Theoretically, it will clear the curb and allow a view of the store windows by the passing motorist.
4. It automatically eliminates "U" turns except at desired points where provision can be made for them.
5. It may slightly increase the number of stalls, estimated at 6%.
6. It will facilitate street cleaning.

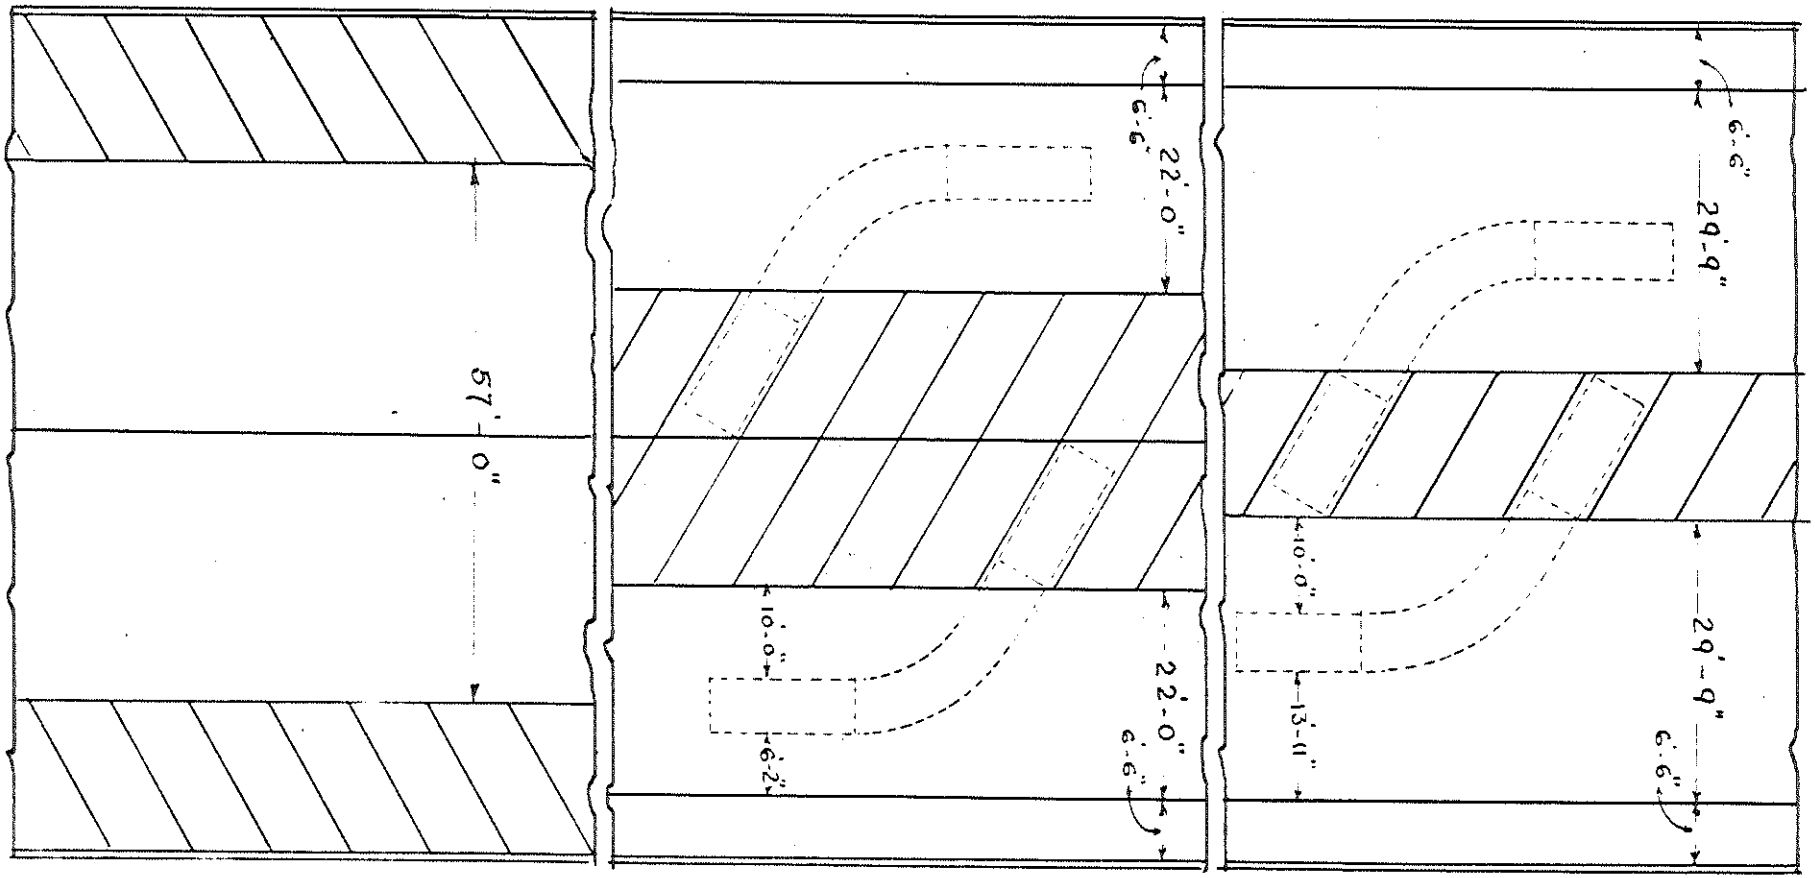
FOR
MAIN STREET
SCALE- 1 INCH = 20 FEET



ANGLE CURB PARKING

DOUBLE CENTER PARKING
STOP AT CURB

SINGLE CENTER
PARALLEL CURB
} PARKING

FIG.- 11

The disadvantages of this plan are as follows:

1. Passengers coming to and from their cars would be obliged to cross through traffic lanes at all points along the block without being protected by any form of traffic regulation. Thus many passengers would be forced to take accident risks that normally are optional.

2. Cars leaving the center zone would have to back out into fast moving traffic lanes. By custom and habit the left hand lane is always the fastest.

3. In the winter time a heavy snow would be much more of a problem than it is with curb parking, because the center of the street would have to be kept clear and the snow would have to be piled at the curb. People would be forced to walk in the street to find a pathway to the sidewalk.

4. To be effective, the plan requires that all curb space be kept clear which would be practically impossible with the present police force.

5. Cars seeking a parking space must travel in a line about ten feet out as shown on Figure 11, and they would therefore slow up traffic if any curb parking or waiting was permitted.

The Poilce Commissioners gave careful consideration to all of these points and decided that in view of the large volume of traffic which Main Street carries, double center parking would create too great an accident hazard. It was pointed out that, while this plan has been successful in a number of smaller cities as far as was known it has not been tried out on streets carrying from twelve thousand to seventeen thousand cars a day. The advantages and disadvantages are listed above for further reference should the plan be considered again.

A third plan called single row center and parallel curb parking overcomes some of the disadvantages of the double row center parking, for example, it would permit short period parallel curb parking say for fifteen minutes without impeding traffic to any

appreciable extent. The accident hazard would be reduced by 50% since only half of the cars are parked in the center of the street. Cars leaving the center parking zone could move forward and turn into the opposite lane of traffic instead of backing out. A slightly steeper angle could be used which would permit an increase in the number of stalls.

The single row center plan offers most of the advantages of double row center parking and fewer disadvantages. Of the two, we would prefer it. For the present at least, the committee felt that angle curb parking as now used with a strictly enforced one hour limit, offered the best solution. This will first be given a thorough try-out.

In closing this subject, it should be mentioned that if a four foot walk in the center of the street were built in connection with double row center parking, the accident hazard would be eliminated, because motorists who desired could walk down to the corner to cross the traffic lanes. Something of this kind may be the ultimate solution.

A resume of the important results and conclusions of the parking study is included at the back of this report.

ADDENDUM TO PARKING STUDY

The Board of Police Commissioners of Middletown has seen fit to adopt a number of the most important parking suggestions derived from this survey. These include one hour parking for Main and Court streets a one dollar fine for minor parking violations, and a number of other changes. Since the traffic survey staff was still intact at the time when these changes went into effect, an exceptional opportunity existed to make a few short parking checks to determine the effect of the changes on the parking habits of the community, the space circulation, and the space available under the new conditions. Accordingly, a parking study was made on one week-day and one Saturday about three weeks after the initiation of the changes.

This data was taken at 15 minute intervals using the same method as in the March survey to get results which would be directly comparable.

Spaces Available-Afternoon Peak Hours

	Week Day			Saturday		
	2 Hour Parking	1 Hour Parking	% Imp.	2 Hour Parking	1 Hour Parking	% Imp.
Zone 1	20	46	130	20	46	130
Zone 2	53	111	109	47	96	104
Zone 3	98	111	13	No Data	No Data	
Main St.	171	268	57	*67	*142	*112

*Main St.- between Liberty and William Streets.

The greatest improvement is noted between Washington and College streets (Zone 1) where the number of available spaces increased from 20 to 46, a matter of 130%. A large increase in available spaces was also noted in Zones 2 and 3 with an average

on the week-day for the entire Main Street of 57%

At the Saturday afternoon peak hours, the average improvment in Zones 1 and 2 is 112%, enough to make a tremendous difference in the ease of parking during this period. When this data was taken the new parking lanes had not been painted in Zone 3 and therefore, no comparison here could be made. However this zone is relatively uncongested and of no great importance in this comparison.

Comparison of Space Turnover

The following tabulation shows the increase in space turnover effected by the new regulation.

LOCATION	TIME	NO. CARS ACCOMMODATED		% INCREASE
	SATURDAY	2 Hour Parking	1 Hour Parking	SPACE CIRCULATION
Zone 1	8 A.M. to	3011	4048	35%
Zone 2	10 P.M.	2601	3013	16
Zone 1 & 2	Peak 2-5 P.M.	1271	1485	17
Zone 1 & 2	Peak 7-9 P.M.	745	1191	60
	WEEK-DAY			
Zone 1	8 A.M. to 6 P.M.	1974	2322	18%
Zone 2	"	1328	1452	10
Zone 3	"	856	957	12
Entire Main St.	"	4158	4731	14

The average increase in Saturday space turnover in Zone 1 for the entire business day from 8 A.M. to 10 P.M. was 35%, an increase of 1037 cars. In Zone 2, the increase was 412 cars bringing the total increase between Liberty and William Streets to 1450 cars or 26%

For comparison during the Saturday peak hours, Zones 1 and 2 were combined. Between 7 and 9 P.M. which is the heaviest parking peak of the entire week, the increase in circulation was 60% a tremendous improvement which should reflect itself in increased business.

The week-day comparison made during the period of the business day indicates a uniform increase in space circulation with an average of 14% for the entire Main Street.

Parking Period Distribution

Parking habits have changed under the new regulation through the re-distribution of parked vehicles. Those who wish to park on Main Street for a short period of time can now do so, while the few who wish to park a longer period are required to park elsewhere. Thus, Main Street is now being used largely by shoppers and those whose business will not require much over one hour, and the east-west streets and Broad Street are being used by those who are employed in the business district, or who may require longer than an hour. The following table, when compared with Figure 3, indicates the changes that have been made. The average parking time is now approximately 10 minutes less than formerly.

Parking Period Distribution (Zone 1)

1 Hour Parking Limit

Average Time Parked	Saturday % Total Cars	Week-Day % Total Cars
15 Minutes	46%	41.7%
30 "	25	26.5
45 "	15.1	15.6
60 "	8.4	7.6
Over 60 "	5.5	8.6
Average Parking time of legally parked vehicles	28 Minutes	28 Minutes

Note that approximately 85% of those parking in Zone 1 stay three quarters of an hour or less, and about 70% stay for only one half hour or less, although they are entitled to one full hour. The percentage of overtime parking, that is over one hour, remains about the same as it was before, but the overtime parkers do not stay for the extended periods that they formerly did. This is due to the excellent enforcement by the police. Naturally with the present police force they can not eliminate all overtime parking.

The number of cars observed parked opposite hydrants, prohibited zones, and driveways in Zone 1 on Saturday has decreased from an average of 65 to 10 under the new regulations.

Conclusions

More motorists are now able to park on Main Street than ever before, and they can now locate parking space much more easily at the desired point. An enormous improvement has been effected during the peak hours especially from 7-9 P.M. on Saturday. There is still some congestion during this period which can only be eliminated by the prevention of all double parking. The new regulation has had the effect of moving long time parkers into parking lots and no limit parking zones. The unrestricted east-west streets still show about the same space circulation as before with a little higher average parking time. About 12 more cars on the average than formerly now park on Broad Street, a negligible increase, except between Court and Washington Street where most of this increase is concentrated. Strict enforcement of the new regulations and the one dollar fine have been very effective in bringing about these vastly improved conditions.

VEHICLE VOLUME ANALYSIS

Middletown, due to its size, location and industries, is what we might call a "representative" city and it therefore presents the usual city problems, one of the most important of which is the control and direction of traffic flow. The correct solution of this problem is of vital importance to any city's growth and welfare. But it is not one which can be solved without a considerable amount of study and statistics.

As shown elsewhere in the report, the registration figures for the Middletown district have increased rapidly during the past ten years. Yet Middletown still has the same Main Street and the same bridge crosses the Connecticut River.

We therefore see that the traffic problem is a very real one and one which will increase rather than diminish in the future.

OBJECTIVES:

A well conducted traffic survey should reveal pertinent data which will enable the proper authorities to:

1. Lay out thru traffic routes.
2. Design streets and intersections
3. Plan future city developement.
4. Make and enforce traffic rules and install regulating signals.

Thru traffic can be classed as positive and negative, that is, helpful or detrimental to the city involved. If such traffic is heavy, clogs up the streets and leaves no money as it passes thru, it is detrimental. If, however, the thru motorist stops, shops, eats or spends money in other ways, it is helpful to the city. It must be decided whether the good derived from the traffic is worth

the additional congestion that it causes, unless there is no alternative route which can be employed. Detrimental traffic should therefore be put thru the city by the best route to eliminate traffic congestion. If possible, the desirable traffic should be so routed that the city reaps the biggest benefit with the least amount of confusion.

Frequently, intersections can be redesigned so that traffic flow is made smoother, is accelerated and is put thru the focal point with less danger of accident. Direction, speed, class of vehicles, pedestrian movement, type of intersection, all have a decided influence on such design. Streets can be widened, parking changed, rules adjusted, or direction of flow altered to induce better traffic conditions. In some cases traffic lights may be more of a detriment than a help. If so, they should be removed.

Older cities, such as Boston, when compared with a city like Washington clearly demonstrate what can be done by city planning. Utility and beauty can be planned for and achieved by proper attention to future needs and development.

Traffic movement that is, volume per hour, is dependent on two factors, number of lanes of traffic and speed of the vehilces. Both are limited by the local conditions. Usually streets must be taken as they are because the width is fixed, but speed is a factor which can be altered. It should be the maximum, consistent with safety. Studies should be made to determine the safe maximum and whether the present regulations, if satisfactory are enforced.

PROCEDURE:

There are a number of methods for making vehicle counts but it is generally agreed that the one which gives the most information for the time and money spent is the "Short Count" method. This system is based on the supposition that a city, from a traffic viewpoint can be divided into areas or sections, each area having a main point through which all traffic passes and minor intersections or feeders which have the same hourly traffic variations as this central point. We can then consider each area separately, designating the central point as a control station and the subpoints as base stations. It has been proved that the traffic from 9 A .M. to 12 noon and from 1 P.M. to 4 P.M. at the base stations will bear the same relation to the 24-hour total as the traffic during these hours at the control station will bear to its 24-hour total. It is obvious then, that, if the control station traffic is taken for twenty-four hours, it will be necessary to count the base station traffic for only a few hours, which count can be multiplied by a factor, to arrive at the approximate base station 24-hour total. This method was employed in the vehicle volume analysis of Middletown.

For the purposes of this count, Middletown was divided into the following zones or areas.

Zone A--Control Station #1 - Main and Pleasant Streets.

Base Stations

8 - Church and High Streets
15 - Main and William Streets

16 - Water and River Streets
21 - Hamlin and William Streets
22 - Church and Broad Streets

ZONE B - Control Station #2 - Main and Washington Streets

Base Stations

#11 - Rapallo Avenue
12 - Main and Liberty Streets
13 - Court and Main Streets
14 - Main and College Streets
23 - Broad and College Streets
24 - Court and Pearl Streets

ZONE C - Control Station #3 - Bridge and Hartford Avenue.

Base Stations

9 - Main and Hartford Avenue
10 - Hartford Ave. and Water Street.

ZONE D - Control Station #4 - Washington and Berlin Streets.

Base Stations

#20 - Mt. Vernon and Wyllys Avenue.
25 - High and Washington Streets
26 - Liberty and High Streets
27 - Grand and High Streets
28 - Johnson and Spring Streets

ZONE E - Control Station #5 - South Main and Warwick Streets

Base Stations

#18 - South Main and Farm Hill Road
19 - Pine and Bretton Road

ZONE F - Control Station #6 - E. Main and Saybrook Road

Base Stations

7 - Russell Street and Ridge Road
17 - Silver and E. Main Streets.

The general practice in taking counts was to start a crew at 6 A.M. on the control station, relieve them at 9 A.M. and use this crew on the base station counts. In addition three other crews worked in seven hour shifts to complete the 24 hour period. This method gave the largest return for the man-hours consumed during the day. Some counts were thrown out due to sudden bad weather during the day when it was felt that the resulting figures would

not give a true picture of conditions.

The base station counts were taken for two one hour periods, the first between the hours of 9 and 12 A.M. and the second between 1 and 4 P.M. Traffic relations between control and base stations are known to be more uniform and representative during these hours.

The control station factor was calculated by dividing the average 24-hour traffic by the average traffic for two hours obtained during the above periods at the control station.

The following table gives the factors at each control point. These factors check closely with those obtained in other cities of similar size.

STATION	AVERAGE 2 HOUR * TRAFFIC	AVERAGE 24 HOUR TRAFFIC	FACTOR
1	1341	10277	7.6
2	1736	14295	8.2
3	1375	11489	8.3
4	497	4408	8.8
5	569	4510	8.0
6	472	3674	7.8
		AVERAGE FACTOR	8.1

* Obtained between the hours of 9-12 A.M. and 1-4 P.M.

Base station 24 hour totals were calculated by multiplying the two hour average at the base station, by the control station factor, the resulting figures are given on the volume count summary sheets. Base station data was used primarily for the development of the flow map, and not in determining percentages of each type of traffic to the total.

DISCUSSION:

A glance at the data plotted on Figures 12, 14, 16, 18, 20, and 21 will reveal characteristics common to all control stations. The lightest travel is always between 4 and 5 A.M. it mounts rapidly after 7 A.M., increasing steadily to attain the peak for the day at 4-5 P.M. An exception is the Connecticut bridge traffic peak, which does not occur until 7-8 P.M. This is probably due to theatre traffic at that time. After midnight, the volume drops down rapidly until it reaches the low point from 4-5 A.M.

Station No.2, Main and Washington Streets, carries the most traffic, an average of 14,295 car per day. Station No. 6 Saybrook Road and East Main Street is low with an average of 3674 car per day.

Volume of Commercial Traffic

The number of commercial vehicles was classified separately at each control station into light trucks, namely those one ton or under, heavy trucks and buses.

Taking Washington and Main Streets as a typical control station, we find the following figures relative to commercial vehicles.

CLASS	AVERAGE 24 HOUR TOTAL	AVERAGE FOR PEAK HOUR	
Light Trucks	442	128	10.A.M.
Heavy Trucks	221	84	11.A.M.
Buses	170	39	3 P.M.
TOTAL	833	251	

As the total traffic thru the Washington-Main Street station is 14,295 cars per day, the total commercial vehicle traffic represents only 6% of the traffic thru this point, a proportion too

small to warrant separate routing. A large proportion of these commercial vehicles are light trucks and probably many of these are engaged in intra-city transportation.

Thru Traffic

Although the figures show that the traffic volume borne by Middletown streets is large, it has not reached the point where resulting conditions are serious or the streets saturated. Probably the summer peaks are at least 40% above those obtained. Even then, the volume does not saturate the streets.

Middletown has an alternate route which can be used and should be planned for in the future. Water Street now carries a very small portion of the traffic (roughly 14%), and because of its parallel location thru vehicles could easily be routed this way to avoid the congestion of Main Street, and to save time. The water front should be developed to improve the appearance of the city and transmit thru traffic.

A fine opportunity for a scenic highway exsists in the development of the river road to Higganum. Thru traffic from the north would then take Water Street to enter this highway, thus avoiding the congestion and accident hazard of South Main Street and the Saybrook Road. It is hoped that the State Highway Department will give serious consideration to this development in the near future.

Let us compare traffic conditions at certain points which appear to be the worst, considering the volume of traffic and the street width. These places are:

Connecticut River Bridge
Hartford Avenue Underpass
Main Street at Washington

The Connecticut River Bridge has a width of 22 feet and carries a daily volume of 6524 cars. The Hartford Avenue Underpass is 35 feet wide and 9776 cars per day pass this point. Main Street has an effective width, allowing for parking, of 53 feet. Traffic here amounts to 14295 cars per day.

Cars Per Hour Per Foot Of Street Width

Bridge	.12
Hartford Avenue Underpass	12
Main Street at Washington	11

This clearly indicates that the bridge and Hartford Avenue at the under-pass are the points of greatest congestion in Middletown, and if we multiply these figures by our estimated 40% increase for summer traffic, some results indicating approaching saturation are obtained. A dd to this, periodic tie-ups of traffic caused by the opening of the draw bridge and we have a very bad condition at the bridge.

Design Of Streets And Intersections

Bridge and Hartford Avenue (Refer to Figure 17.)

This is one of the worst intersections in Middletown. Traffic from Hartford meets cars coming off the bridge, most of which make a left turn at this point. During the average twenty-four hours, there are 2863 cars coming off the bridge, turning to the left and meeting with the 5154 cars arriving on Hartford Avenue. Only 597 cars from the bridge make the right turn to Hartford.

The recently approved Russell loop will do much to relieve this congestion, but the only complete solution is a new bridge across the Connecticut River to replace the present relic of the horse and buggy days.

Main and Washington Streets (Refer to Figure 15.)

This intersection averages the largest volume of traffic in the city, 14,295 cars in twenty-four hours. On the other hand, the traffic on Washington Street crossing Main is comparatively light. The figures show 166 cars crossing from east to west and 132 from west to east. Making a right turn from Main to Washington Street. west are 1148 cars. It would be logical to allow a right turn at the red signal on Main Street for south bound traffic turning into Washington Street. This would materially increase the efficiency of the intersection by speeding up the Main Street movement.

Main and Union Streets (Refer to Figure 13.)

Main Street extension will help this intersection a great deal. The average daily traffic shows 2304 cars per day making the left turn from Main Street to Union Street. These turns will be eliminated to a large extent. A traffic signal will be needed at this point when this extension is completed, and right turns into Pleasant Street on the Red light should be allowed.

In the event that the Main Street extension is not put thru, it would still be advisable to install a traffic signal at Main and Union Streets if the city adopts the plan for a synchronized system outlined in the Traffic signal Analysis section. At present 43% of the vehicles passing through this intersection must make awkward left turns around the rotary. With the installation of a traffic light the rotary could be eliminated which would make these left turns much easier and they would be under control. The signal could be timed so that cars entering Main Street from Pleasant and Union Streets would be approximately in step with a continuously moving band of traffic.

Church and South Main Street (Refer to Figure 13.)

The rotary traffic circle now used at this intersection is a little larger than necessary and slightly too far south. It is suggested that this rotary be moved from 5 to 10 feet north to allow east bound Church Street traffic an easier turn around the rotary. If the size of the rotary is reduced at the same time no hardship will be placed upon traffic turning from Church Street into South Main Street or upon traffic turning from South Main Street, west into Church Street. This change has already been put into effect with satisfactory results.

Saybrook And East Main Street.

When the Main Street extension has been completed, this intersection will be so radically changed that it is useless at this time to make any recommendations. Afterwards, a short study of this intersection should be made to prevent accidents, possibly by the location of a "STOP" signal or boulevard stop signs.

Berlin and Washington Streets (Refer to Figure 19)

There are four directions of travel converging at this point. Traffic on Washington Street east and west, and Berlin Street is comparatively heavy, while on Park Place and the Terrace it is light. Let us look at the figures

24 Hour Averages

Washington Street East	3926
Washington Street West	2777
Berlin Street	1281
Park Place	445
Terrace	417

In the summertime traffic volume figures at this point obtained by the State Highway Department indicate that there is 40% more traffic than in the winter when the above counts were made. A few suggestions relative to eliminating accidents are covered in the accident analysis section of this report.

ACCIDENT ANALYSIS

The rapid increase in the number of accidents in the last few years is worthy of serious consideration by those interested in motor vehicle traffic and by the general public whose safety while travelling by automobile is gradually reduced from year to year. We are rapidly approaching the time when drastic measures must be taken either in the form of restrictive legislation or an intensive educational safety campaign for the general public. While the following study only includes 164 accidents, there were undoubtedly many times this number unrecorded minor accidents. Many of these might just as well have been of a major character except that the participants were a little more fortunate.

Unless the accident involves personal injury or property damage amounting to at least twenty-five dollars, it goes unrecorded, and therefore a study of this kind can only cover those accidents which were important enough to be recorded. Many of the minor accidents are probably very important in their implications as to highway conditions and driving habits, and it is unfortunate that insufficient data make a study of them possible.

OBJECT:

The purposes of the accident analysis were as follows:

1. To determine the high--accident location.
2. To determine the causes of accidents at these points.
3. To ascertain whether or not highway conditions contributed to the cause of an accident.
4. To make recommendations which would decrease the accident hazard.

PROCEDURE:

The accident reports filed with the Police Department and the State Motor Vehicle Department for the years of 1932-33-34 were the basis of this analysis. From these reports, lists of intersection and "mid-block" accidents, in the order of seriousness were prepared. Then data on these accidents was condensed on cards and special analysis sheets covering the location, date, time light or dark, condition of weather and road, nature of the accident, extent of injuries, and type of collision.

Whenever possible the cause of the accident was ascertained based on the report as a whole, the diagram, and testimony of the driver or drivers involved.

Out of 164 accidents studied, ninety-seven occured in mid-blocks and sixty-seven at intersections. Very few of the mid-block accidents could be accurately analysed because no one point showed sufficient concentration of accidents. The following locations were analyzed in detail.

1. Connecticut River Bridge and Hartford Avenue.
2. Hartford A venue and Water Street.
3. Main Street and College Street.
4. Main Street and Washington Street.
5. Park Place, Berlin and Washington Street.
6. Washington Street at the R.R. Underpass.
7. Connecticut River Bridge.

Collision diagrams were made of the first six and later reference will be made to them. A tabular summary of all accidents analysed is included on the following page.

SUMMARY OF ACCIDENTS ANALYZED

Discussion of Results and Recommendations

The accidents occuring on the Saybrook Road, the Durham Road, and the Meriden Road, were not thoroughly analysed, because it was impossible to pin them down to a specific location. Their major cause seems to be excessive speed, and carelessness on the part of the drivers. Speed limiting signs placed at speed tempting points such as Bible Rock Hill, Durham Road by Dooley's Pond, and Chapman Hill, on the Meriden Road, would probably help to reduce accidents at these points.

Connecticut River Bridge and Hartford Avenue

Four common causes have contributed to the accidents occurring at this intersection. They are, inattention of the driver or pedestrian involved, failure to grant the right of way, skidding, and cutting in. Little can be done at this intersection under present conditions to remedy the situation, except to move the rotary about three or four feet to the south. This would give cars coming off the bridge turning south an easier and shorter turn, thus preventing them from crowding into the south bound traffic on Hartford Avenue. Reference to the collision diagram Figure 22 will illustrate this point.

Hartford Avenue and Water Street

Of the five accidents at this intersection, see Figure 23, two were caused by turns into Water Street from south bound lane on Hartford Avenue, and two were caused by cutting in from Water Street to north bound lane on Hartford Avenue. While it is undesirable to prohibit south bound cars from entering Water Street a warning sign worded as follows; Cars Bearing Left "SLOW" would help the situation.

A "STOP" sign should also be placed on the north bound lane of Water Street at Hartford Avenue.

Intersection - Main And College Streets.

There were five accidents at this intersection, as indicated on collision diagram Figure 24. In two cases the signal light was in favor of each car. In one case a pedestrian accident, the pedestrian attempted to cross the street against the light and driver was extremely careless in cutting the corner too sharply. Obviously, carelessness on the part of the driver or drivers caused most of the accidents here.

Main Street And Washington Street.

At this intersection there were nine accidents, three of which involved pedestrians. Refer to collision diagram Figure 25. In one case a pedestrian was crossing the street against the light. In three other cases, the cause was due to the hurrying drivers who jumped the amber signals. Such accidents would be reduced if the "STOP" and "GO" signal lights flashed amber following the green only. Carelessness on the part of the driver or drivers caused most of these accidents.

Park Place And Washington Street.

At Washington Street and Park Place all of the accidents occured at or near the rotary as illustrated by Figure 26. Three of the accidents involved cars travelling east on Washington St. and cars coming south from Berlin Street. "STOP" signs placed at Berlin Street and at Park Place would undoubtedly reduce this cause of accidents.

INTERSECTION OF

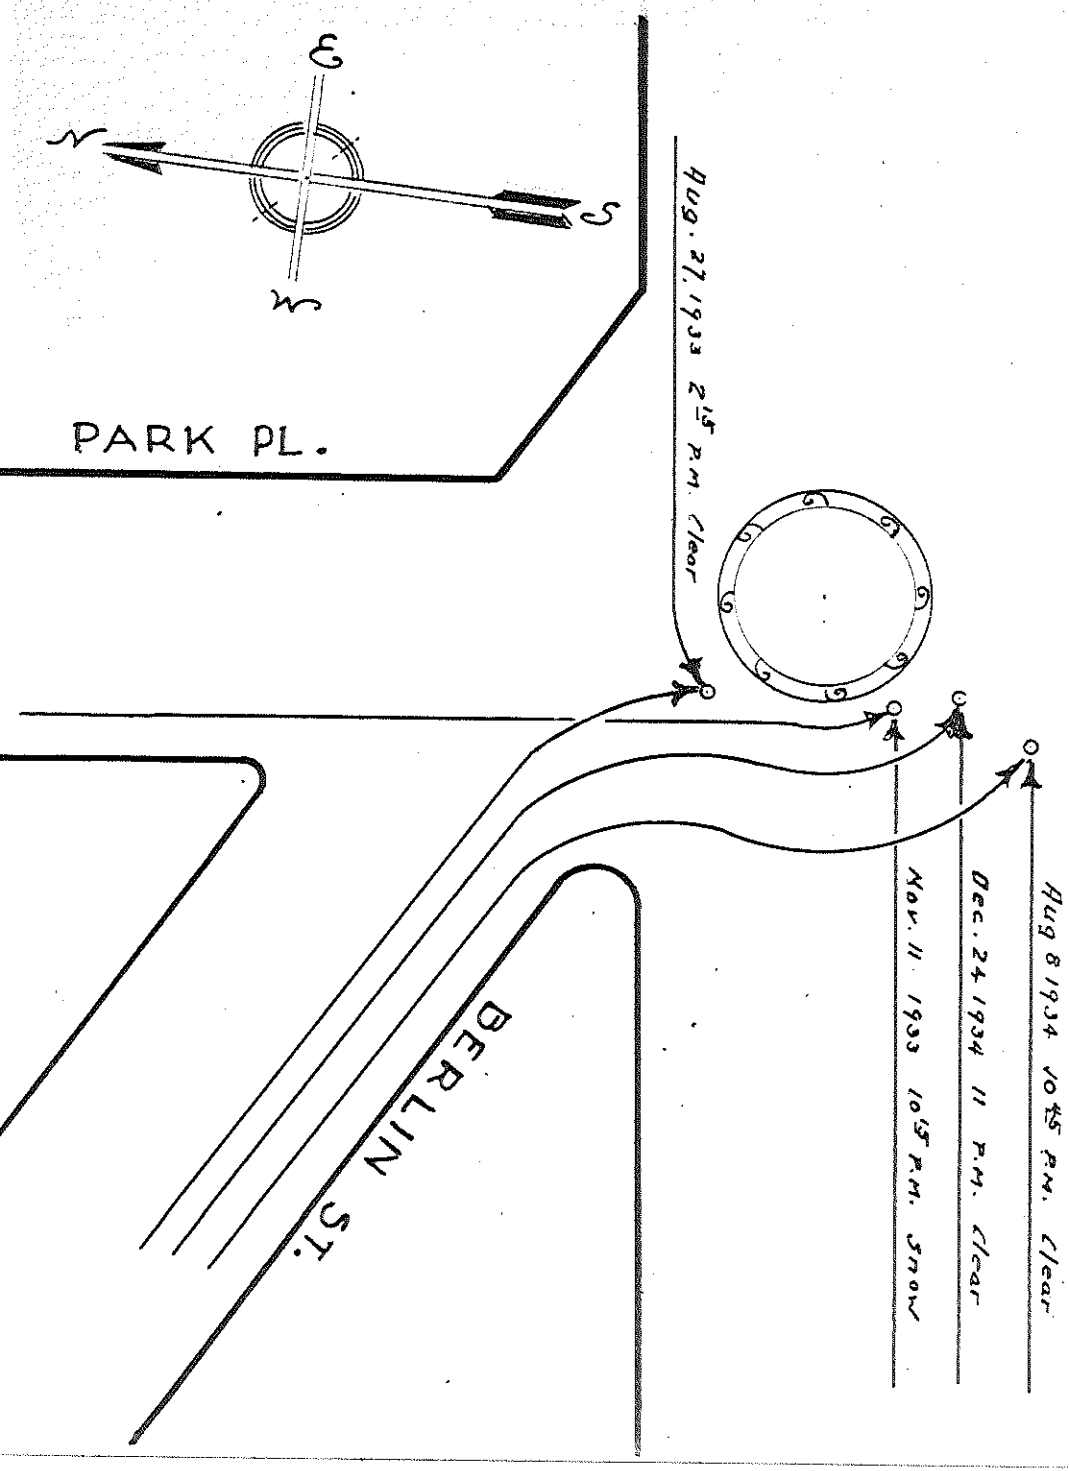
PARK PL. — BERLIN ST.

AND

WASHINGTON ST.

SCALE - 1 INCH = 20 FEET



LEGEND

Path of Motor Vehicles

Point of Contact

Rotary

FIG-26

Cars entering the city travelling east on Washington Street should be slowed down by the time they reach this intersection. Speed limit signs at one or two points between the Underpass and Berlin Street are recommended.

Washington Street At Underpass.

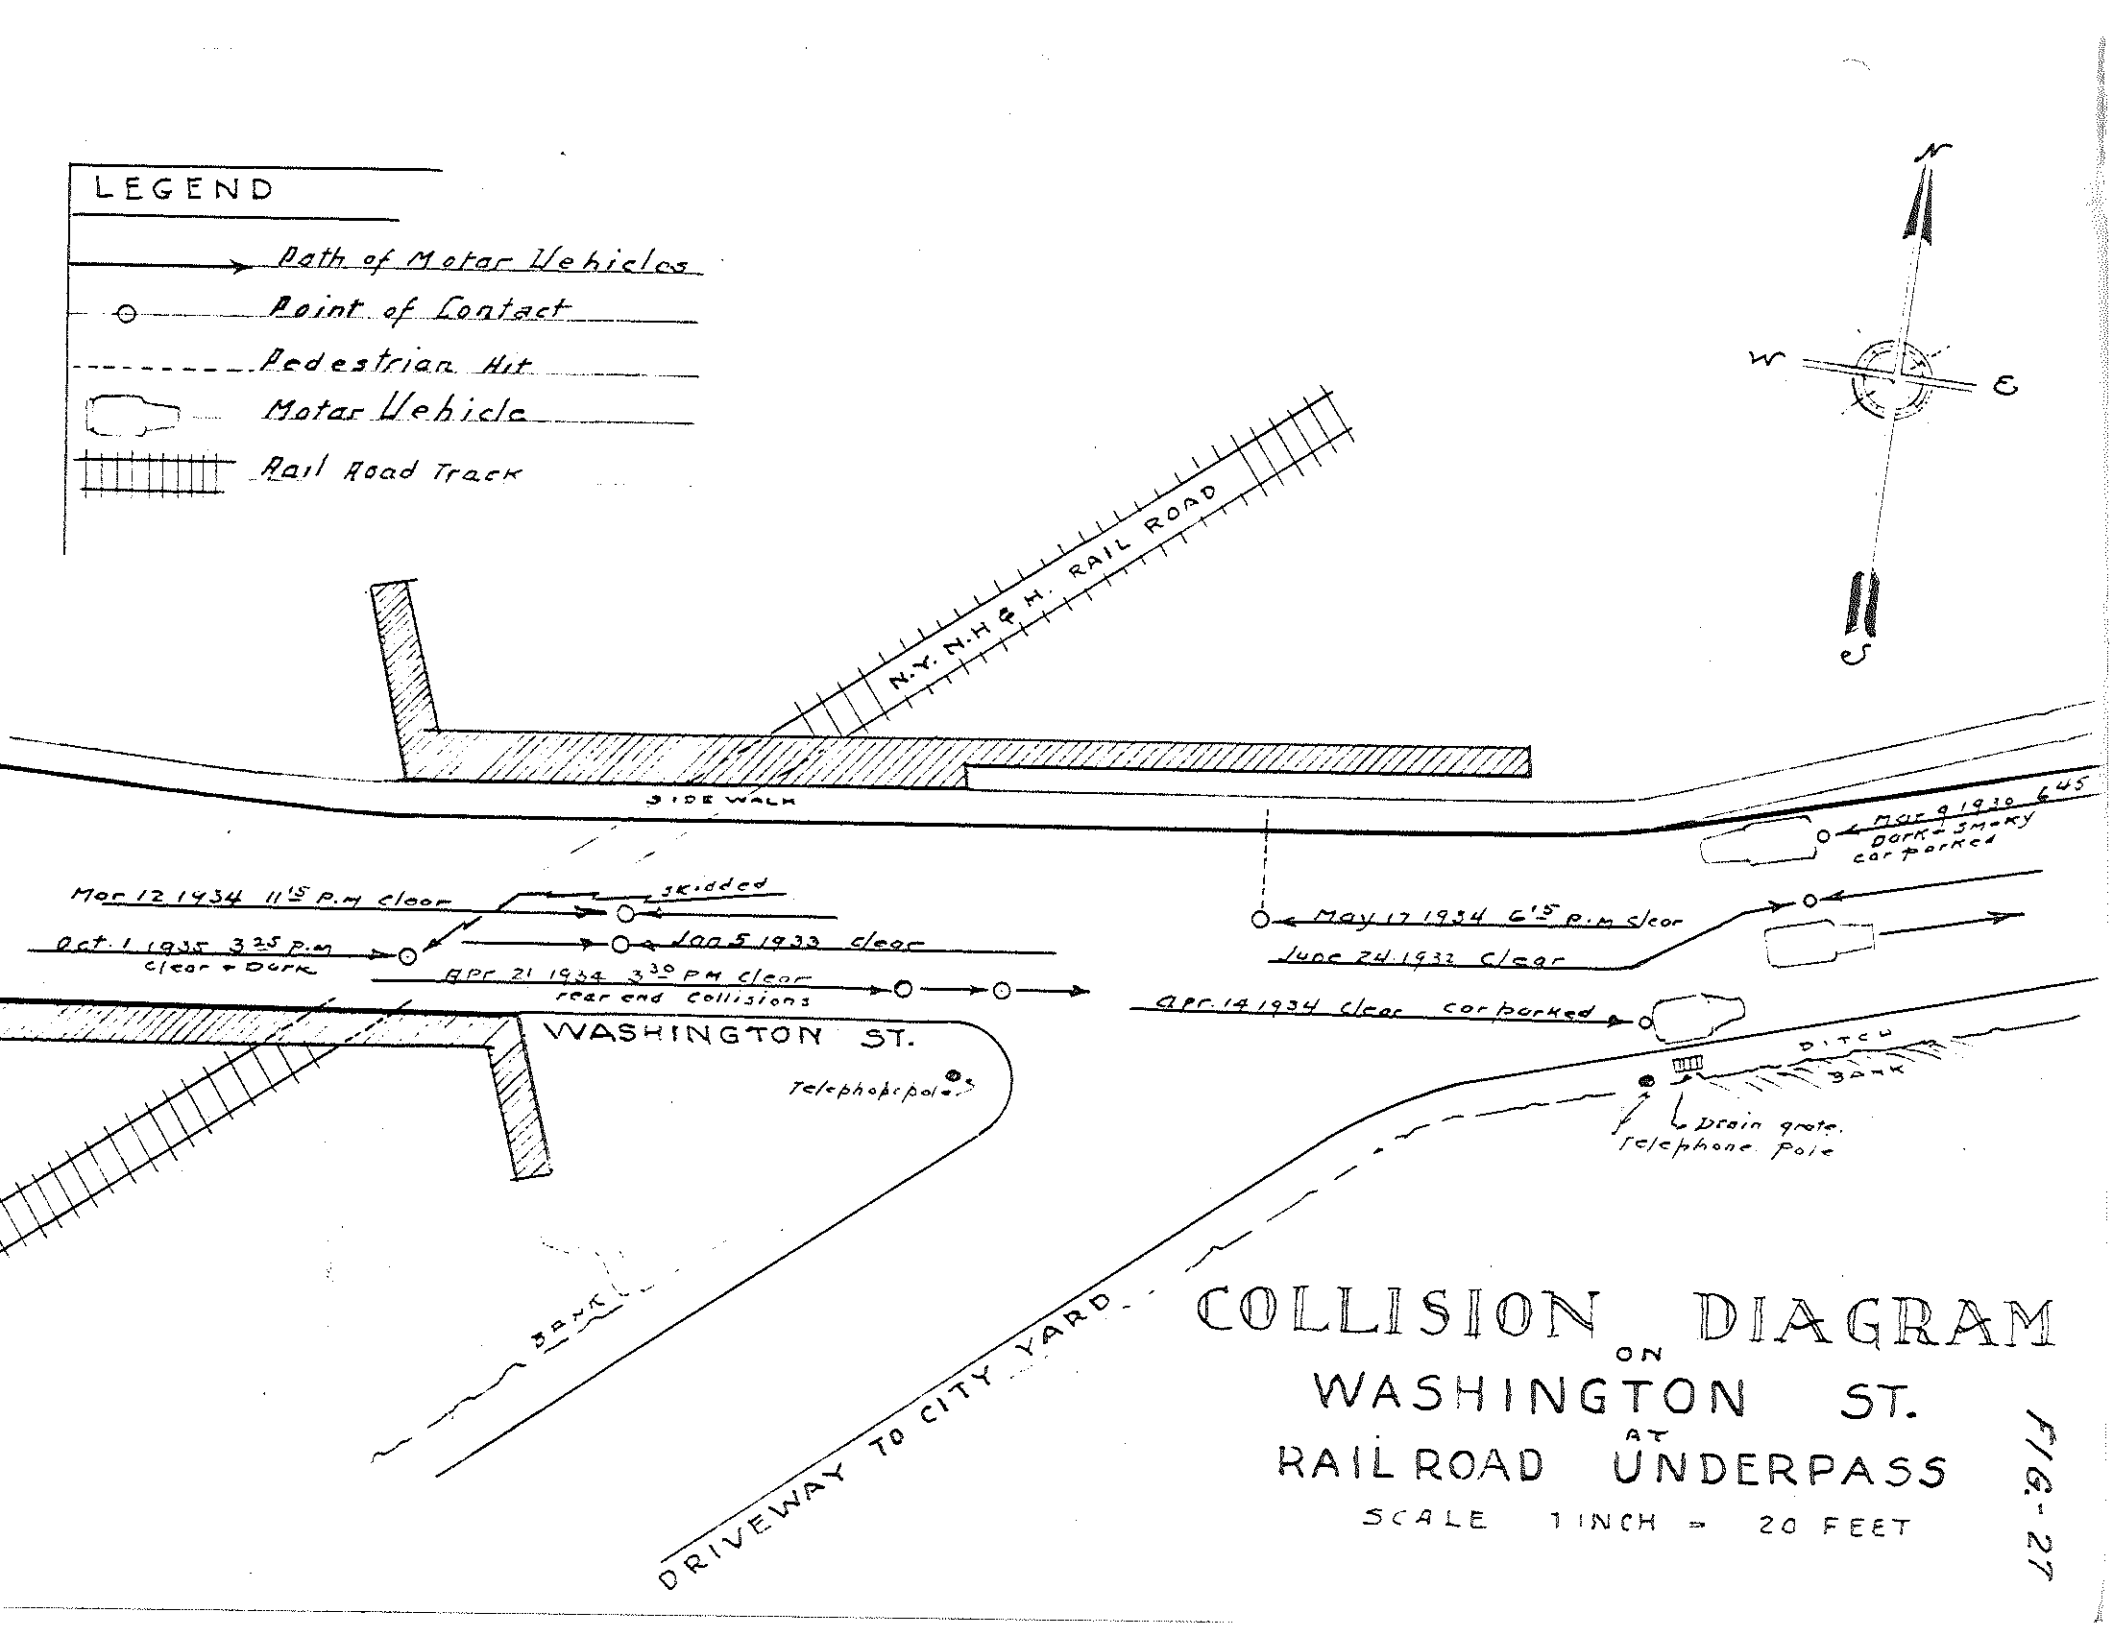
Fifty per cent of the accidents at this location were due to side swiping and to driving on the wrong side of the road. A study of the collision diagram Figure 27 will show that the slight curve and the narrowness of the road are important contributing conditions. Widening of the Underpass is the logical remedy, but if this is too expensive an undertaking, speed limiting signs should be placed at the approaches of the Underpass. The old trolley tracks should be removed as they are likely to cause skidding.

Connecticut River Bridge.

Approximately ninety percent of the accidents on the bridge were rear end collisions caused by skidding and following too closely, and ten per cent were due to defective equipment. At the present time the bridge is equipped with warning signs that the bridge is slippery when wet, but these signs are too small and not conspicuously placed. Better location of these signs plus the warning to keep thirty-five feet apart would undoubtedly decrease the accident hazard on the bridge.

GENERAL CONCLUSIONS:

It should be noted that twelve per cent of the accidents analysed were due to inattention of the driver, fifteen per cent due to failure to grant the right of way, eight per cent were



COLLISION DIAGRAM

WASHINGTON ST.
AT
RAILROAD UNDERPASS

SCALE 1 INCH = 20 FEET

FIG. 27

caused by operating on the wrong side of the road, eighteen per cent were due to skidding, eighteen per cent were due to following the preceeding car too closely, nine per cent occurred when the operators made improper left turns in opposition to traffic, six per cent were due to defective equipment, and ten per cent occurred when operators backed carelessly.

This report clearly shows that about seventy-eight per cent of the accidents studied were caused by carelessness. In order to eliminate this large source of accidents, it is obvious that the public must become better acquainted with the principles of safe driving.

Accident Spot Map

In order to make this study as useful to the police as possible, an accident spot map was prepared showing the location of all accidents in the* Middletown records during the year 1934. On the small copy included on the next page these accidents are classified as fatal, pedestrian, and ordinary accidents, which may involve either property damage or personal injury. Since it was desirable to include a large territory on this comparatively small map, a uniform scale could not be used at all points.

A larger map prepared for the use of the police has colored tacks to indicate the various types of accidents. This will be displayed in a prominent position for continual reference by interested members of the department.

* The Motor Vehicle Department records contain 231 cases. A few unimportant ones were omitted.

SCHOOL CHILD TRAFFIC HABITS

School children are universally recognized as a community's greatest asset and everything possible should be done to protect them from traffic hazards. While the accident rate for school children in Middletown compares favor ably as far as we can determine with other cities, it is hoped that the facts revealed by this survey will show ways and means of still further improving the safety of Middletown children.

OBJECT:

A study of school child traffic habits was made to determine.

1. Data on good and bad habits of children walking to and from school, for use of school authorities in promoting safety practice.
2. The location of dangerous intersections.
3. The location and motorist observance of "STOP" and "SLOW" signs in the school district.
4. Motorist habits at the intersection in question.
5. Constructive suggestions to increase the safety of school children.

PROCEDURE:

A crew of men were stationed at all intersections within a quarter mile radius of the school during the school hours, one day being allotted to each school. The habits of the children were observed on the following points:

1. Crossing at corner.
2. Crossing in the middle of the block.
3. Walking in the street.
4. Playing in the street.

Motorists travelling thru these intersections were observed as to speeding, obedience of zone signs, and general safety practice.

DISCUSSION:

We will take up the figures obtained for each school or group of school separately.

Central School and Middletown High School

About 90% of these children have no dangerous habits in going to and from school. However 4% do cross in the middle of the block and 5% to 7% walk or play in the street. Thus, there are 10% of the children who do not properly conduct themselves to insure safety

In connection with the vehicle traffic it should be noted that from 12% to 14% do not obey "STOP" signs. This lack of observance is clearly dangerous and is discussed at length under "Stop Sign Observance".

A detailed study at the points of heaviest school child movement was made to determine the characteristics of the traffic on each individual street. It will be noticed by a study of the data sheets at the end of this section that the percentages vary considerably according to conditions. For instance, on College Street near Hamlin we have 43.2% of the children, crossing in the middle of the block, and walking or playing in the street. However on Hamlin near College, there are only 2.1% of the children, who do this. The most dangerous points near these schools due to the habits of the children and the traffic are:

1. Hamlin at College Street.
2. College at Pearl Street.
3. Pearl at College Street.
4. Pearl at Court Street.
5. Court at Pearl Street. (East)

There do not seem to be any corners in this district where the traffic is heavy enough to warrant the use of a Police officer but the use of "School-Boy" monitors would promote safety at the above intersections.

Johnson School

The degree of laxness relative to crossing in the middle of the block and walking or playing in the street is about the same here as at the Central School. The worst accident hazard in this district is at Liberty Street where 81 children a day cross Main Street. In the traffic signal section of this report, the removal of the Liberty Street signal is discussed, because of the low volume of cross traffic. While the number of children crossing here is small, they should have ample protection from the heavy Main Street traffic.

St. Mary's School

Here a large number of children are crossing in the middle of the block or walking in the street at the intersection of Hotchkiss and Church Streets and at Church and South Main Streets. This condition should be corrected by safety education.

Woodrow Wilson High School

The study of the conditions surrounding this school were hampered by the fact that very few streets have sidewalks and it is therefore necessary for the children to walk in the street. Walking in the street induces playing in the street and these facts must be borne in mind in studying the resulting data.

It is impossible to correct this condition fully without going to the expense of installing sidewalks. These children should be impressed with the fact that by walking in the street they increase the accident hazard, and therefore they should be unusually careful. The traffic on these streets is not heavy, but on Russell Street there is some speeding.

Hubbard School

On Silver Street at Elm, Wall Street at Silver, Walnut Street at Silver Street, and Silver Street at Evergreen Avenue, it can be noted that a large number of children are walking and playing in the streets. Since the traffic at these points is light and the children in the street are not in much danger, nevertheless, it should be eliminated so far as possible by safety education of the children.

St. John's School and McDonough School

Of the number of children observed going to and from these schools there were 221 walking in the street and 165 playing in the street. While this is only 10% of the children recorded, it is a large number and should be reduced to avoid accidents. A total of 386 children in the street every day affords plenty of chance for a serious accident.

The traffic density on the streets leading to these schools is q uite heavy.

Durant School

Of the intersections studied in this school district, there are only two which have sidewalks on the streets; Lake Street at Durant Terrace and South Main Street at Pameacha.

This would account for the large number of children walking

in the street. However, this condition is also true at Lake Street and Durant Terrace where there are sidewalks.

Evidently the children in this district get in the habit of walking in the street and do not use sidewalks even when there is opportunity to do so. Safety education as at the Wilson School is suggested.

The following summary gives a general idea of habits observed in each school district, and indicates what points should be stressed in a safety education program. Further details are given in the accompanying data.

SUMMARY

PERCENTAGE OF CHILDREN OBSERVED

IN VARIOUS STREET PRACTICES

SCHOOL ZONE	CROSS AT CORNER	CROSS MIDDLE BLOCK	WALKING IN STREET	PLAYING IN STREET	NOTES
Central School and Middletown High	88.3	7.4	2.6	1.7

Referring to the major traffic infractions, there were 101 cases in 1934 as compared with 89 cases in 1933 with a slightly high percentage of convictions than in 1934. Note that in 1934 42% of the minor violators were fined while 76% of the major violators were convicted, indicating a much higher degree of enforcement in the major cases. A more detailed study of the major traffic infractions can be made by referring to the accompanying tables.

Comparing the percentage of fines collecting for overtime parking in the years 1933 a nd 1934, the data shows that in 1933 87% of those apprehended were required to pay the fine while in 1934 only 37% paid the fine. This indicates that during the past year there has been some slackness in the enforcement of the overtime parking regulations, and a very unsatisfactory situation has developed because the 37% who were fined knew that many others had been able to avoid it. The clerk of the court who collects the fines for this offense has had a very difficult job because of the terrific pressure exerted by parking violators trying to avoid payment of the present two dollar fine.

In other cities a one dollar fine which has to be paid by every one regardless of their position and influence in the community has proved to be more satisfactory.

It is recommended that the fine for all parking violations be reduced to one dollar and that no fines be remitted except by the order of the court. This recommendation has already been adopted by the Board of Police Commisssioners and is now in effect. Under the new plan the clerk of the courts position becomes much easier.

THE TRAFFIC SIGNAL SYSTEM

For a number of years it has been recognized that the present traffic signal system does not adequately handle Main Street traffic. Traffic control is essentially a problem of keeping traffic moving continuously by arranging it in an orderly procession and eliminating all unnecessary stops. The speed at which traffic may move safely should be determined by the physical condition of the streets, block lengths, and density of traffic. The timing intervals now used have been adopted after years of experience with Main Street traffic and they probably are the best that can be obtained with the existing equipment, most of which is now about ten years old.

This study had three definite objectives:

1. To analyse each Main Street intersection to find out whether or not the present traffic signals are needed and if there are any intersections where traffic signals should be added.
2. To discover if any improvement can be accomplished with existing equipment both with and without the addition of new equipment.
3. To consider the application and total cost of new equipment permitting a continuous moving flow of traffic throughout the entire length of Main Street.

After considering all the phases of traffic movement on Main Street, it has been decided that all traffic signals as now installed are necessary with the possible exception of Liberty Street where a stop sign has been proposed instead of the signal, which was installed about a year ago, shortly after a serious pedestrian accident at this point. The Johnson school studies indicates that approximately 80 school children necessarily cross Main Street at Liberty Street each school day in going to and from school. It

does not seem advisable to leave them without some form of protection in crossing Main Street at a point which averages nearly 11, 000 cars a day, second only to Washington Street in volume of traffic. See traffic flow map. Therefore, unless a traffic officer can be assigned to Liberty Street during the school hours it would be better to let the signal remain.

When the Main Street extension has been completed, the traffic characteristics at the Union Street intersection will be quite different from those observed in this survey. As near as can be estimated, four to five thousand cars a day will travel straight ahead at this intersection. At present, there are 4600 cars a day entering from or leaving to Pleasant Street, which will be unaffected by the change. A large portion of the present Union Street traffic will be carried by the new extension leaving the Union Street traffic at an estimated two to three thousand cars a day. Obviously some form of traffic regulation will be required at this intersection preferably a traffic signal.

If this suggestion is adopted, it is recommended that a green arrow be installed coinciding with the red signal for south bound Main Street traffic to allow right turns against the red light. Thus all traffic from Main Street to South Main Street would be uninterrupted. The physical layout of the intersection is excellent for this arrangement.

Another point where a green arrow could be used to advantage is at Washington Street allowing south bound Main Street traffic to make a right turn against the red signal. The adoption of this suggestion would not create a serious accident hazard because the

amount of pedestrian traffic crossing Main Street on the north side of Washington Street is comparatively light. Should these suggestions be followed, it will be necessary to eliminate two or three parking spaces so that the right turning traffic can travel closer to the curb before turning.

The present signal equipment consists of a 1500 watt timer with four signals located at Washington Street, Court Street, College Street, and William Street operating to-gether on the same time cycle and a 550 watt timer operating the two signals at Grand Street and Liberty Street to-gether on the same time cycle. There is no relation between the two timers or means of synchronizing them in any way to permit a continuous flow of traffic.

These two timers contain a series of automatically operated switches which throw the green, amber, and red signals on and off in a predetermined cycle. Additional equipment could not be installed to synchronize them.

The 1500 watt timer operates the four principal signals on the following time cycle; Green 55 seconds, amber overlapping gree 3 seconds, red 25 seconds, amber overlapping red 3 seconds. The total period of the cycle and the proportion of red to green can be changed at will.

With existing equipment it would be possible to accomplish progressive travel from William Street through Washington Street by reversing the connections at two of the signals, say at Colleg and at William Street in such a way that these two signals would show red when the other two signals showed green. The total perio

would then have to be approximately 90 seconds with 45 seconds red and 45 seconds green which would allow continuous travel thru these four blocks at approximately 20 miles per hour. The principal objection to this time cycle is that it necessitates the same green and red time for the cross streets as for Main Street. A longer or shorter period could be used, but in any case it would have to be the same for both the green and the red lights and 45 seconds has been determined as about the best time interval. This change would not synchronize these lights for continuous travel with those at Liberty and Grand Streets, but it would eliminate the necessity of the thru motorist making more than one stop in passing thru the four principal signals. While the above plan is not recommended as a permanent or entirely satisfactory solution, it might be worth a trial pending the purchase of new equipment which would accomplish the same result thruout the entire length of Main Street with flexible control.

New Equipment for Continuous Traffic Movement

In considering a traffic signal system for continuous movement, it has been assumed that a signal will be necessary at the intersection of Main and Union Streets as soon as Main Street extension has been completed. Then if the whole system of seven lights was not synchronized, a motorist would frequently be stopped as many as four times in passing from one end of Main Street to the other, in which case he would require about 215 seconds to make the trip. A synchronized system permitting continuous travel at twenty miles per hour would at the most require 145 seconds, a saving of 70 seconds per car. It is estimated that from 2000 to

2500 cars a day pass through Main Street without stopping except to obey signals. Obviously a continuous system would save a great deal of time and contribute a great deal toward motoring ease and satisfaction in the course of a year. The time spent waiting for signals on Main Street plus the idling expense for gasoline now costs the motoring public at least twenty thousand dollars a year more than it would with a continuous system.

A number of technical advantages are: The bands of continuously moving traffic would tend to eliminate traffic tie-ups due to the accumulation of cars waiting for traffic signals. Vehicular speeds could be instantly controlled to meet varying conditions from police headquarters where the master timer would be located. The system would ordinarilly be set for an average speed of about twenty miles per hour, and cars travelling too fast would soon be stopped by a red signal while cars travelling too slow would not be able to make the signals. A thru motorist would be required to make only one stop or possible none at all depending on whether or not he approached the first signal at the right time. Main Street would more easily handle a large volume of traffic. Sundays, when practically all of the traffic travels straight through the lights could be set for a higher average speed. Should it be necessary cross streets carrying different amounts of traffic could be given a different time split.

With the proposed system, an amber signal could be used following or overlapping the green signal only. This would be a great improvement over the present sequence because the amber signal would only be used to warn cars in motion that a change was coming.

Cars at a standstill waiting at a red light would not receive an amber signal following the red, which encourages starting before the green light actually appears.

A schematic wiring diagram of the equipment required for progressive travel of Main Street traffic is shown on Figure 28. With this arrangement the signals could be operated in pairs with one secondary timer for each pair, except for the signal at Union St., thus saving of the cost of three secondary timers. The master control is used to keep the secondaries in their proper relation to each other, giving complete control of the entire system from one point. Normally the master control would be located at police headquarters and secondary controls would be pole-mounted at desired points on the street.

Figure 29, is a space-time graph showing the proposed setting of the timers to produce a progressive movement of traffic on Main Street at twenty miles per hour. With these settings it would be possible for the last car of a given group to enter the intersection twenty seconds after the first car had started and still make all the lights. Technically, this is called a twenty second band which is considered very satisfactory. Under heavy traffic conditions it usually takes a maximum of fifteen seconds to clear an intersection of traffic after the signal has turned green, therefore twenty seconds provides ample leeway for extreme conditions.

The horizontal solid lines on the graph indicate the time period of the red signals at each intersection. The parallel diagonal lines indicate the bands of traffic flowing on Main Stree

LAW ENFORCEMENT ANALYSIS

Law enforcement of both minor and major traffic violations is naturally a most important phase of any system of traffic regulation for lax enforcement of good regulations will completely nullify the benefits to be derived from them. Obviously, proper enforcement by the courts goes hand in hand with the work of the Police and the proper functioning of one is of little use without the proper functioning of the other.

OBJECT:

The object of this analysis was to determine how many traffic violations had been reported by the police during the years 1933 and 1934 and how these had been disposed of by the courts.

A ll information on these points was taken from the police records and tabulated on the following sheets into two general classifications. First, minor traffic infractions which were handled by the collection of a fine by the clerk of the court, second, major traffic infractions which because of their na ture were court cases.

A study of the following tabulation of the minor infractions indicates that more violators were apprehended during the year 1934 than in 1933, but that fewer fines were collected in 1934. In 1933, 190 fines were collected out of 239 violations, a total of approximately 80%, while in 1934, 127 fines were collected out of 304 infractions, a total of 42%. The percentage fined for each type of minor infraction is given in the a ccompanying tables, if more detailed analysis is desired.

ANALYSIS OF ENFORCEMENT OF MINOR TRAFFIC INFRACTIONS (1934)

VIOLATIONS	FINED $2.	FINED $1.	NOLLED	PENDING	TOTAL	PER CENT FINED
Overtime Parking	53	17	84	25	189	37%
Improper Parking	3	1	2	3	9	44
Double Parking	14	3	12	5	34	50
Parking on Cross Walk		1		1	2	50
Parking in Restricted Area	6	3	4	10	23	40
Parking on Wrong Side of Street	1			16	17	6
Obstructing Drive-Way	2		2	1	5	40
Passing Stop Sign	15	3	5	1	24	75
Passing Signal	5				6	83
TOTAL	99	28	109	72	304	42

ANALYSIS OF ENFORCEMENT OF MINOR TRAFFIC INFRACTIONS (1933)

VIOLATIONS	FINED	NOLLED	PENDING	TOTAL	PER CENT FINED
Overtime Parking	87	12		100	87%
Double Parking	29	7		39	80
Passing Stop Sign	11	1		12	91
Parking in Restricted Area	10	3		13	76
Improper Parking	21	10		31	68
Parked on Wrong Side of Street	32	12		44	73
TOTAL	190	45		239	79.5

Referring to the major traffic infractions, there were 101 cases in 1934 as compared with 89 cases in 1933 with a slightly high percentage of convictions than in 1934. Note that in 1934 42% of the minor violators were fined while 76% of the major violators were convicted, indicating a much higher degree of enforcement in the major cases. A more detailed study of the major traffic infractions can be made by referring to the accompanying tables.

Comparing the percentage of fines collecting for overtime parking in the years 1933 a nd 1934, the data shows that in 1933 87% of those apprehended were required to pay the fine while in 1934 only 37% paid the fine. This indicates that during the past year there has been some slackness in the enforcement of the overtime parking regulations, and a very unsatisfactory situation has developed because the 37% who were fined knew that many others had been able to avoid it. The clerk of the court who collects the fines for this offense has had a very difficult job because of the terrific pressure exerted by parking violators trying to avoid payment of the present two dollar fine.

In other cities a one dollar fine which has to be paid by every one regardless of their position and influence in the community has proved to be more satisfactory.

It is recommended that the fine for all parking violations be reduced to one dollar and that no fines be remitted except by the order of the court. This recommendation has already been adopted by the Board of Police Commisssioners and is now in effect. Under the new plan the clerk of the courts position becomes much easier.

in both directions. Technically, the slope of these traffic bands is an exact measure of the speed of the vehicles passing along the street. The steeper the slope of the bands, the faster the speed and vice versa. With this signal sequence note that it is impossible for a vehicle to travel much too fast or much too slow without immediately running into a red signal. At the same time, there is enough leeway to allow for momentary delays or ordinary variations in speed. Between Washington Street and Grand Street a faster rate of travel possibly 25 miles per hour would be desirable and this can be accomplished under the proposed plan without difficulty.

COSTS

None of the present equipment can be used except the signals and the signal cable. One new signal would have to be purchased for Union Street unless it is decided to move the Liberty Street signal to this point. The plan illustrated in Figure 28 calls for one master timer, four secondary timers, one traffic signal, two auxiliary green arrow signals for Washington and Union Streets and 2500 feet of No. 12 seven conductor cable.

Quotations obtained from the manufacturer of the city's present equipment, and estimates on the installation cost supplied by the Connecticut Power Company indicate that the total cost of the above equipment and its installation would be approximately $2000.00 Complete correspondence on this subject is on file at the office of the Director of Public Works.

MOTORIST OBEDIENCE OF SIGNALS

Careful observance of signals by all motorists is absolutely essential to the safe movement of vehicles and pedestrians thru an intersection. Minor violations such as jumping the amber lights are responsible for a large percentage of the accidents occurring at intersections controlled by signals.

This study was made with two definite objectives. First, to determine the percentage of cars entering the intersection on each phase of the signal cycle. Second, to determine the percentage of potential violators by considering only those who approach the intersection at a time when the signal could be disobeyed. For example, the majority of cars waiting for the signal to turn green are not necessarily in the front row and therefore, they are not in a position to jump the signal. The same is true at the other phases of the signal cycle.

For the first study every car was recorded as it entered the intersection according to the light showing at that time. Three Main Street intersections were checked between the hours of 10 A.M. and 4 P.M.

The average percentage of cars entering on each phase of the signal for the three intersections are as follows. For further details refer to the accompanying data sheet.

	Middletown	Average for Connecticut Cities
Enter on Green	95.6%	94.9%
" on Amber after Green	2.0%	1.9%
" on Red	.9%	1.9%
" on Amber before Green	1.5%	1.3%

Comparing these results with those obtained by the department of Motor Vehicles in 1934 in representative cities of the state as

listed in the right hand column above, Middletown's obedience is slightly better than the state average, particularly obedience of the red light.

The second part of the study involving only potential violators brings out the amber light obedience much better because it shows the percentage of motorists who would disobey the amber light if they were in a position to do so. Observers counted only those cars in the front row waiting for the green light, and those cars who could deliberately enter the amber after the green light when they had plenty of time to stop.

Table of Potential Disobedience

	Amber before Green	Amber after Green
Entering Cars	26%	39%
Strict Obedience	74%	61%

It is evident that a large number of motorists are potential violators and particularly significant that 26% jump the green light when they are at a standstill and have no occasion to do so. The 39% who entered the amber after the green can be excused to some extent because the purpose of this amber is to clear the intersection. A publicity campaign or an enforcement campaign by the police to reduce the violations of the amber signals would do much to reduce the accident hazard at the principal Main Street intersections.

If a new signal system is installed as suggested in another section of this report, the wiring at these signals can be changed to show amber after the green only which will greatly reduce the number of cars who jump the green light. The light will then change directly from red to green, and if the lights are properly shielded no warning of the green light will be given until it actually appears. This is now universally recognized as the best sequence

PEDESTRIAN OBEDIENCE OF SIGNALS

The traffic lights are designed for two purposes, to control traffic and to control pedestrians. Naturally, their efficiency depends to a great extent on the observance of these lights by the vehicles and pedestrians. To determine the percentage of pedestrians who obey the traffic lights, a detailed study was made on Main Street at the corners of Liberty, Washington, Court, College and William Streets.

Four observers were stationed at each intersection with one man at each corner. Each observer picked out one pedestrian at a time, watched the light as he stepped from the curb, noted whether the light changed or not during the pedestrian's progress across the street, its color when he reached the opposite sidewalk and whether the pedestrian was hampered by traffic.

DISCUSSION:

In analysing the figures shown in the accompanying tables it should be remembered that the unfavorable lights for the pedestrian at the start of the crossing are amber after green, and red. A person stepping from the curb on amber after green is sure to be caught in the path of the traffic after three seconds, when the light turns red. Stepping into the street against the red signal is a direct violations of the traffic rules, and a dangerous practice.

The following condensed tabulation will give a clear understanding of the essentials. For further details refer to the accompanying tables

INTERSECTION	STREET	PERCENTAGE OF PEDESTRIANS STEPPING FROM CURB ON AMBER AFTER GREEN	RED
Main and Liberty	Main	0	37
	Liberty	3	52
Main and Washington	Main	1	29
	Washington	4	33
Main and Court	Main	3	16
	Court	6	32
Main and College	Main	4	24
	College	7	30
Main and William	Main	2	18
	William	8	44
AVERAGE		3.8	31.5%

This summary shows that while the percentage of people stepping from the curb on amber after green is small, the number starting to cross on red is large, averaging 24.8% on Main Street and 38.2% on the east-west streets. These crossings are in driect violation of traffic rules, dangerous to the crossing pedestrians interfere with traffic, and constitute a traffic hazard which should be removed.

It is possible to a djust the signals for a longer amber or walk period, but because of the width of Main Street such a change would be of little value unless a much longer period, say 12 to 15 seconds, were used. If pedestrians could be educated to start only on the green light, their crossings would be made with no danger.

The present traffic light system is amply able to take care of the pedestrian flow. But the public should be educated by a program of publicity, calling their attention to the hazards of present observance of the traffic lights.

BOULEVARD STOP SIGN OBSERVANCE

A large number of boulevard stop signs are located at street intersections in Middletown to secure greater safety for converging cars. This study was made to determine how well these signs were being obeyed by the motorist.

In order to secure accurate data, the observer was stationed a small distance away from the sign and usually sat in a car to prevent his being seen by the motorist. The conduct of the drivers was divided into three classes, no stop, slow, and stop. Several of these locations were checked at daylight, dusk and dark to find out if the time of day influenced stop sign obedience.

The accompanying data sheets show a large number of cars which did not stop or which merely slowed down. The average percentage of obedience for all boulevard stop signs observed was:

	Middletown	Average of 40 Cities in Connecticut
No Stop	24%	8.5%
Slow	53%	19.4%
Complete Stop	23%	72.1%

Comparing these figures with those obtained by the Motor Vehicle Department in forty different municipalities during 1934, Middletown is far behind other cities in the state in boulevard stop sign obedience. Only 23% of the motorists in Middletown come to a complete stop as compared with the state average of 72%. In Middletown, 24% make no pretense of stopping as compared with 8½% for the state. However, 53% in Middletown slow down thereby observing safety practice to some extent.

Intersections showing the highest percentage of stop sign disobedience are:

	NO STOP	SLOW	STOP
Pameacha Ave. at Highland Ave.	26	52	22
High Street at Liberty	19	74	7
Pearl Street at Spring	10	80	10
Pearl Street at Grand	47	33	20
Center Street at Water	33	42	25

There does not appear to be any great difference in the percentage of observance for daylight, dusk and dark, except a tendency toward less stirct observance after dark.

This overwhelming lack of stop sign obedience in Middletown obviously creates an accident hazard which must be eliminated. Cars on thru streets guarded by stop signs expect crossing motorists to stop and do not exercise as much caution as they otherwise would. Therefore, stop signs which are not being observed are worse than no stop signs at all. These signs should be either enforced or removed.

STUDY OF U-TURNS

An unusual feature of Middletown's traffic is the number of U-turns made on Main Street. The average city does not and cannot allow reverse turns on their main thoroughfare. But Middletown with its very wide street can do so, although many people question the desirability of this privilege.

This study was made to determine, the number of these turns, their object, whether or not they were dangerous, and the extent to which they impeded traffic flow.

During the business hours of one week-day and two Saturdays, men were stationed, two to each block, to record the number of U-turns on the sheets provided for that purpose. Each car making a reverse turn was watched to find out whether it turned to park or to reverse direction, to-gether with the number of cars delayed by the turn and the length of time that they were delayed.

DISCUSSION OF RESULTS:

From the accompanying data it is evident that there were a very large number of U-turns on Main Street, both on week-days and Saturdays, the average number of U-turns per hour being 152. Of this number 30% turn to park and 70% to reverse direction. During the 18 hours studied there were 2559 cars held up by 678 of the U-turning cars, which is 21% of the total. The remaining 79% did not impede traffic. The average number of cars delayed at one time was four and the delay averaged five seconds. Most U-turns were made from 3 to 5 P.M. On Saturday nights the peak comes at 8 to 9 P.M.

Ordinarily, U-turning cars do not hold up traffic as much as might be supposed, but they do constitute a menace to safety especially during periods of heavy traffic. The one hour parking limit just put in force may decrease these turns, because more parking spaces will be available and hence the number of cars turning to park will be decreased.

Three courses of procedure are open. First, all U-turns can be eliminated with no provision for turning around. Second, all U-turns can be eliminated and green arrows installed to allow right turns on the red signal, thus making it easy for traffic to go around the block. Third, U-turns can be permitted at designated points such as at or near intersections when the Main Street signals are red.

The first two possibilities do not offer a real satisfactory solution, because of the unusual length of Middletown's blocks. The third might be adapted to Main Street by creating U-turn zones at the end of each block. A double white stop line could be placed about 20 feet from the pedestrian cross walk which would create a lane between cars waiting for the signal and the crosswalk, for cars wishing to make U-turns. It is recommended that serious consideration be given to this plan.

SPEED STUDIES

Motor vehicle speeds have increased with the development of automobiles and roads to a point undreamed of ten or fifteen years ago. This has increased accidents to an alarming extent and has made high accident locations out of roads which were formerly considered perfectly safe. Therefore, it is important for the police of every city to know the speed habits of the public at all points in their city.

The purpose of this study was to make speed checks at selected points and to classify passing vehicles as to type and speed.

Observers using stop watches and 45 degree mirrors were stationed at the various points for periods ranging from two hours up. The box containing the 45 degree mirror located 176 feet from the observer indicated the passage of a vehicle by a flash. In this way, the time required for each car to travel 176 feet could be accurately measured with a stop watch and the speed calculated. Speeds were measured at thirteen key points in the city, their locations being recorded on the accompanying data sheets.

For the purpose of classification, vehicle speeds were divided into the following groups: 0-25 miles per hour, 25-35 miles per hour, 35-45 miles per hour, and 45-55 miles per hour. Whenever possible, the speed of every passing vehicle was measured but in cases where the traffic was too heavy vehicles were selected at random.

South Main Street

At Highland A venue and South Main Str eet 49% of the passenger cars were travelling from 35 to 45 miles per hour and 15% from 45 to 55 miles per hour. A speed of 45 miles per hour or over is too high at this point. Furthermore, the light and heavy trucks have a tendency to travel too fast at this location.

At St. Mary's School on South Main Street 26% of the passenger vehicles were travelling between 35-45 miles per hour, which is a little too high for safe city driving. A bout the same situation or worse exists at Hunting Hill Avenue, Pameacha Avenue and at Lake Street on South Main Street.

Russell Street

There is some speeding at Russell Street near the Wilson High School but it could be classified as excessive since only 12% of the passenger vehicles were observed to travel over 35 miles per hour. An occasional check up by a motorcycle policeman would be advisable on account of the school.

Main Street

Most of the traffic on Main Street travels below 25 miles per hour except for occasional speeds. Between College and William Street 50% were travelling over 25 miles per hour and 5% over 35 miles per hour. With these few exceptions, Main Street traffic is operating at a reasonable speed.

Washington Street.

East of the underpass on Washington Street is an especially

bad location for speeding, and the data indicates that 39% of the vehicles here were travelling over 35 miles per hour. This is a high accident location and speeds should be held down to 30-35 miles per hour at all points on Washington Street east of the underpass.

Hartford Avenue (In Cromwell)

Forty-seven percent of the passenger cars were observed to be travelling between 35-45 miles per hour just north of the bridge and 10% were travelling between 45-55 miles per hour. While this stretch is not considered a high accident location it may become so if speeding over 45 miles per hour is not checked.

It is suggested that the following points be patrolled from time to time by the police to check excessive speeding; South Main Street between St. Mary's school and Highland Avenue, Russell Street near the Wilson School, Washington Street east of the underpass, and Hartford Avenue north of the bridge. For further details refer to the following tabulations which show the speeds of passenger cars, heavy trucks, light trucks, and buses at the various points and the total number of vehicles measured.

PEDESTRIAN COUNT

This study was made to determine the number of persons crossing the streets at each intersection on Main Street. To do so, all pedestrian movement was counted between 9 A.M. and 6 P.M. at all Main Street intersections on one week-day and one Saturday.

The accompanying tabulation of results reveals the following information:

On Saturday the busiest crossing on Main Street was the east side of Main Street at Washington Street where 10,255 people were counted. College Street was second with 6683 and Court Street was third with 6100, these also being on the east side of Main Street. In general, the east side of Main Street at the busy intersections carries from three to ten times as many people as the west side.

The busiest east-west street crossing on Saturday was the south side of Court Street where 3982 people were observed, the next busiest was the north side of Court Street with 2150 and the third busiest was College Street. A study of these data quickly reveals the necessity for traffic signals to protect pedestrians at all of these intersections.

The week-day results are somewhat different. Then the largest number of pedestrians were observed on the east side of Main Street crossing College Street. Washington Street was second and Court Street third. On week-days there is not so much difference between the east and west sides of Main Street, although the east side shows more people at every intersection.

TOTALS	1596	1755	2193	2193	2974	2504	2379	3955	3005	2009	24563

These figures which can be analysed in detail by referring to the tables should be of great interest to those who are in business on Main Street.

SUMMARY OF IMPORTANT CONCLUSIONS

The following conclusions are not intended to be a complete summary. Only the most important general conclusions are given here. For further details and minor suggestions refer to the text of each section.

PARKING:

1. One hour parking on Main Street plus strict enforcement is the best practical way to relieve the parking congestion and get the desired space turn-over.

2. Parking should be eliminated on the south side of Court Street during the business day, and one hour parking should be allowed on the north side, between Broad and Water Streets.

3. The overtime parking fine should be $1.00 instead of $2.00 with no exemptions except thru the discretion of the judge.

VEHICLE VOLUME ANALYSIS:

1. Water Street should be improved and used as an alternate route for thru traffic.

2. The river road to Higganum offers an excellent opportunity for the developement of a scenic highway for thru traffic along the river, eliminating the congestion and accident hazard of East Main Street and the Saybrook Road.

3. The Middletown-Portland bridge should be replaced. It is now the bottle neck of the Middletown traffic system.

4. Middletown truck traffic is not heavy enough to warrant separate routing.

ACCIDENT ANALYSIS:

1. Seventy-eight percent of the 164 accidents studied were caused by carelessness in one form or another. Safety propaganda is recommended.

2. The highest accident locations or streets are along South Main Street and along Saybrook Road, although these roads seem to be comparatively free from serious accident hazards.-

SCHOOL CHILD TRAFFIC HABITS:

1. School monitors or some system of supervised traffic could be used to advantage at certain points in the central school district. See text.

2. A program of safety education at regular intervals is suggested at all the schools, particularly at the Durant and Wilson Schools where the lack of sidewalks makes the safety problem more difficult.

3. The Liberty Street light furnishes protection to school children crossing Main Street, and it should not be removed, unless traffic officers can be stationed here during school hours.

THE TRAFFIC SIGNAL SYSTEM:

1. The traffic signals should be synchronized to allow progressive travel on Main Street. Total cost $2000.00

2. When Main Street extension has been completed, a signal will be necessary at the corner of Main and Union Streets. It should be synchronized with the other lights to allow continuous travel. Right turns against the red light indicated by a green arrow should be allowed, south bound Main Street traffic turning into Union Street, and south bound Main Street traffic turning into Washington Street .

3. The use of the amber after the green light only is recommended.

SIGNAL OBEDIENCE:

1. Motorist obedience of the signals is reasonably satisfactory and compares favorably with the degree of obedience in other Connecticut Cities.

2. Most of the non-observance comes from jumping the amber lights before and after the green. Stricter enforcement would reduce accident hazards from this source.

3. The disobedience of signals by pedestrians is too high. It constitutes an accident hazard which should be corrected.

BOULEVARD STOP SIGN OBEDIENCE:

1. Disobedience of Stop signs is much higher in Middletown than in other Connecticut Cities. Stop signs should be enforced or removed.

U-TURNS:

1. The U-turn problem is a difficult one with no real satisfactory solution. See text. Because of the long blocks in Middletown, and the wide Main Street, a very large number make use of this privilege.

SPEED STUDIES:

1. The dangerous points for speeding (see text) should be patrolled at regular intervals.

PEDESTRIAN COUNT:

1. On Saturday, the highest concentration of pedestrians was observed on Main Street at the east crossing of Washington Street.

2. The east side of Main Street carries from three to ten times as many people as the west side.
